## CASE RECORDS OF THE

### MASSACHUSETTS GENERAL HOSPITAL

#### 1948

---

The date of publication of any case may be determined from the case number. The first two figures of each case number indicate the volume number, 34. The third and fourth figures give the number of the week, dating from January 1. The last figure gives the case number for the week. For example, Case 34251 is the first case for the twenty-fifth week of Volume 34.

- Abscess of brain, multiple, 34201
  - of lung, 34392, 34422
  - appendiceal, 34102
  - Brodie's, of tibia, 34381
  - pelvic, 34112, 34201, 34452
- Actinomycosis of chest wall, 34412
- Addison's disease, 34092, 34502
- Adenoacanthoma of fundus of uterus, 34271
- Adenocarcinoma, see Carcinoma
- Adenoma of kidney, papillary, 34041
  - of liver, 34402
  - of trachea, with extension into thyroid gland, 34352
- Adrenal gland, amyloid degeneration of, 34261, 34531
  - atrophy of primary (cortex), 34092
  - sarcoma of (fibro-), 34511
  - tuberculosis of, 34502
- Amyloidosis, of adrenal gland, 34261, 34531
  - of kidney, 34261, 34531
  - of liver, 34531
  - of spleen, 34261, 34531
- Aneurysm, mycotic, of coronary artery, with rupture, 34441
- Anomaly, congenital, of aorta, right-sided, with persistent truncus arteriosus, patent interventricular septum, persistent fifth aortic arch, left, 34161
  - of bile duct, 34132
  - of spine (spina bifida occulta), 34131
  - of terminal ileum (duplication), 34292
 (See also Heart)
- Aorta, anomaly of (right-sided), 34161
- Appendicitis, acute, with perforation, 34052, 34102
  - gangrenous, with abscess, 34102
- Arthritis, rheumatoid, 34531
- Ascites, chylous, 34031
- Aspiration of amniotic fluid, massive, 34182
- Atresia, congenital, of hepatic and cystic duct, 34132
- Atrophy of adrenal gland (cortex), 34092
  - of pancreas (acinar tissue), 34512
- Bile duct, atresia of, congenital, 34132
  - carcinoma of (adeno-), 34251
- Bladder, carcinoma of (papillary), 34472
- Bone, abscess of, Brodie's (tibia), 34381
  - carcinoma of, metastatic, of humerus, 34162
  - of rib, 34262
  - myeloma of, multiple, 34362
  - osteoma, osteoid of (femur), 34501
  - tumor of, Ewing's (sacrum), 34012
- Bone marrow, leukemic infiltration of, 34062
- Brain, abscess of, multiple, 34201
  - carcinoma of, metastatic, subarachnoid space, 34192
 (See also Sinus)
- Bronchiectasis, 34022
- Bronchitis, chronic, 34512
- Bronchus, carcinoma of, 34022, 34091, 34142, 34241, 34422
  - metastatic, 34021, 34151
- Carbon tetrachloride intoxication, 34221
- Carcinoid of ileum, 34431
- Carcinoma of ampulla of Vater (adeno-), 34251
  - of bile duct (adeno-), 34251
  - of bladder (papillary), 34472
  - of brain (subarachnoid space), metastatic, 34192
  - of bronchus, 34022, 34091, 34142, 34241, 34422, 34481
  - metastatic, from breast, 34021
  - from kidney, 34151
  - of colon (adeno-), 34172
  - of duodenum (adeno-), at ampulla of Vater, 34251, 34301
  - of esophagus, metastatic, from breast, 34021
  - of gall bladder, 34102, 34291, 34332
  - of humerus, metastatic, 34162
  - of kidney (renal-cell), 34262
  - of liver (hepatoma), 34351
    - with extension into portal and hepatic veins, 34011, 34521
  - metastatic, 34021, 34031
  - of lung, metastatic, 34031
  - of lymph nodes, metastatic, from breast, 34021, 34031
  - of ovary, metastatic, 34031, 34281
  - of pancreas, 34231, 34321, 34452
    - (tail) with invasion of spleen, adrenal gland and stomach, 34152
  - of parathyroid gland, 34491
  - of rib, metastatic, 34262
  - of sigmoid, with abscess formation and extension to pelvis and uterus, 34112
  - of sinus, sphenoid (transitional-cell), 34482
  - of stomach (adeno-), 34082, 34341
    - mucous (signet-ring), 34171

## FOCAL EPILEPSY

### A Statistical Study of Its Causes and the Results of Surgical Treatment

#### II. Epilepsy Secondary to Cerebral Trauma and Infection\*

JAMES C. WHITE, M.D.,† CHING TUNG LIU, M.D.,‡ AND WILLIAM JASON MIXTER, M.D.§

BOSTON

THIS is the second of two papers reviewing surgical experience with 240 epileptic patients at the Massachusetts General Hospital in the decade 1935 through 1944. These patients in whom the epileptogenic focus could be localized clinically and visualized at operation therefore amount to 21 per cent of the total 1130 hospital admissions for epilepsy. In the preceding paper the relation of seizures to tumor of the brain was discussed.<sup>1</sup> Tumors are the most important etiologic factor in this group of epileptic patients with a local operable condition, since approximately a third of those in whom such lesions were situated above the tentorium had convulsions. One hundred and sixty tumors made up two thirds of the total operable cases. This paper considers the role of cerebral trauma and infection, with material based on 80 patients.

The modern surgical attack on epilepsy due to focal injury of the brain dates back to the pioneer work of Professor Otfried Foerster<sup>2</sup> on gunshot injuries of the brain in German soldiers of World War I. Penfield, who studied with him in Breslau in 1927, has made the greatest advances and written the outstanding monograph on the subject with Erickson, describing the technic and results in the extensive series of cases from the Neurological Institute in Montreal.<sup>3</sup> As pointed out in the preceding paper, special interest began to be focused on this group of patients with focal epileptogenic lesions<sup>4</sup> at the Massachusetts General Hospital in 1935. Air studies, either by pneumoencephalography

or by ventriculography, have been carried out routinely throughout this period, and electroencephalography since 1937. Penfield's method of mapping the cerebral cortex of the patient under local anesthesia with the thyratron stimulator has been used in these operations. In the last year of World War II the development of a cortical electrode holder and of the technic for "activated electroencephalography" on Dr. A. Earl Walker's<sup>5</sup> service at the Cushing General Hospital has provided a still more effective method of delimiting the area from which the epileptogenic discharge originates, but it is not safe to draw conclusions from such recent operations. We have therefore selected the decade 1935-1944 for statistical review because it gives a follow-up period from a minimum of two years up to a possible maximum of twelve for the evaluation of surgical results.

#### MATERIAL

Out of the total 80 patients submitted to exploration for seizures that were believed to have resulted from trauma or infection, 62 are available for statistical study of end results. These include 49 cases of acute or chronic seizures resulting from cerebral trauma and 13 following infection (Table 1). The remaining 18 cases were excluded for various reasons. Follow-up study was inadequate in 6. Three other patients turned out to have brain tumors (these cases are described below). In 7 with previously verified abscesses, 1 with cortical resection for athetosis and 1 with a subcortical hematoma following rupture of a cerebral aneurysm, operation for complicating mild seizures was not considered necessary. Epilepsy due to widespread cortical atrophy, diffuse degenerative disease, hydrocephalus and the hereditary forms of the disease is not suitable for surgical treatment, and failure to find operable lesions in some of the cases described below was due primarily to our lack of sufficient appreciation of this fact in the

\*Presented at the annual meeting of the Massachusetts Medical Society, Boston, May 25, 1948.

†From the Neurosurgical Service, Massachusetts General Hospital.

‡Assistant professor of surgery, Harvard Medical School; chief Neurosurgical Service, Massachusetts General Hospital.

§Resident in neurosurgery, Graduate Hospital of the University of Pennsylvania; formerly research fellow in neurosurgery, Massachusetts General Hospital.

¶Member, Board of Consultation, Massachusetts General Hospital.

Although the type of epilepsy observed in the great majority of these patients was the classic Jacksonian focal seizure, some had generalized attacks and others only hallucinatory auras. The petit mal form of epilepsy, however, rarely if ever starts from a superficial focus and is therefore not amenable to surgery.

Thyroid gland, goiter of, colloid, with cystic formation, 34252  
 Tibia, abscess of (Brodie's), 34381  
 Trachea, adenoma of, with extension into thyroid gland, 34352  
 Tuberculosis of adrenal glands, 34502  
   of endometrium, 34282  
   of lung, 34261, 34502  
   of lymph nodes, 34502  
   of Fallopian tube, 34282  
 Tumor, Ewing's, of sacrum, 34012  
 Ulcer of duodenum, acute, 34122  
   chronic, 34072  
   of esophagus (peptic), 34462  
 Uterus, adenoacanthoma of fundus of, 34271  
   endometritis, 34282  
   normal, 34042  
 Varix of esophagus, with rupture, 34402, 34432  
 Vein, extension of hepatoma into (portal and hepatic), 34011, 34521  
   phlebitis of, thrombo-, 34172  
   thrombosis of (popliteal), 34242  
   mesenteric, 34382  
 Vertebra, carcinoma of, metastatic, 34031  
   chordoma of, second and third lumbar vertebrae, 34511

work despite occasional nocturnal seizures. In this patient circumscribed softening in the arm area was also present. A man who required evacuation of a subcortical clot in addition to a large subdural collection suffered mild sensory attacks every four to six months for two years, and has subsequently remained free for four years. Another, who in addition to a small subdural hematoma had a large subcortical clot with considerable contusion to the neighboring area of the brain, developed seizures for the first time six weeks after operation. In this case the chronic epilepsy, which has continued for the past two years, cannot be ascribed to the subdural hemorrhage, since an extensive cerebral cicatrix remains. Although subdural hematomas, if uncomplicated and evacuated early, are not likely to cause residual epilepsy, we have found trapped pockets of yellow fluid in the course of three operations for chronic epilepsy, which were probably residua of former extravasations of blood into the subdural space. One of these patients had had a hematoma evacuated one year previously.

*Cortical compression from depressed fractures*  
Acute compression of the underlying cortex by simple depressed fractures of the cranial vault may lead to rapid onset of focal seizures. This was encountered in 6 of a series of 54 cases of these lesions. In each case there was definite cortical compression by the depressed cranial fragments, and the result of decompression by their elevation or removal was prompt and permanent disappearance of the seizures. This fortunate result is ascribed to the fact that in each of these civilian injuries the dura remained intact and the underlying cortex presumably was not lacerated, so that there was no permanent meningocerebral cicatrix or focal injury of the cortex to lead to late chronic epilepsy. Early removal of the compressing fragments, especially if in the vicinity of the motor cortex, is essential to prevent the formation of a cortical scar and a high incidence of chronic epilepsy. The following case report serves to illustrate this situation.

A 5-year-old girl riding her tricycle fell over an embankment and suffered a left temporoparietal depressed fracture (Fig 1). She was briefly unconscious and then had a lucid interval. An hour later she again became comatose and developed twitching movements of the right side of the face and the right extremities. These soon became continuous, the coma deeper, and the respirations slow and labored. Exploration without anesthesia revealed a subgaleal hematoma and two large angulated fragments of bone, which deeply depressed the intact dura. As soon as these were elevated the convulsive movements ceased. There was no evidence of residual damage to the brain, and the patient left the hospital 10 days later in excellent condition. A recent follow-up letter, 5 years later, states that she is a nervous, maladjusted child at school, but has had no convulsive seizures.

Of the severer wartime injuries reported by Ascroft,<sup>9</sup> even when the dura was not torn, 23 per cent were followed by chronic seizures. This incidence, however, was only half as high as that when the dura was penetrated. When the underlying

dura is torn and the cortex lacerated, especially in the presence of indriven fragments of bone or infection, even though the acute seizures may clear up, there is high incidence of chronic epilepsy. This amounted to 45 per cent in the best military statistics of World War I (Ascroft<sup>9</sup>), although indriven fragments were removed and damaged cortex radically sucked away. Injuries of this type are followed by scar formation and frequently result in recurrent seizures for this reason. It is a matter

FIGURE 1 *Comminuted Depressed Temporoparietal Fracture, Which Caused Acute Status Epilepticus. Continuous seizures ceased as soon as the depressed fragments were elevated.*

of major concern to the United States Veterans Administration that there are listed 15,000 cases of craniocerebral injuries in which the patients have survived the present war, nearly half of whom may develop chronic seizures (Watson<sup>10</sup> and Bailey<sup>11</sup>).

#### *Chronic Epilepsy Following Cerebral Injury*

This series of 28 patients with chronic epilepsy due to cerebral scars, on whom operation was undertaken and adequate follow-up obtained, is subdivided as follows: cortical scars or areas of local atrophy (microgyria) following cranial injuries, 27 cases, and postoperative epilepsy following cortical resection, 1 case.

earlier years of this decade. In some previous reports<sup>3</sup> the surgical epileptic cases have been subdivided on the pathological basis of expanding lesions and focal scars. In such a classification the intracranial hematomas and acute abscesses have been included with the neoplasms. In this review it has seemed best to discuss the actual tumors as a separate group.<sup>1</sup> We are therefore classifying the

TABLE 1 *Classification of Epilepsy after Cerebral Injury and Infection in 62 Patients Selected for Statistical Analysis*

LESION	No. of CASES
Epidural hemorrhage (early or acute epilepsy)	5

Acute seizures	9
Chronic seizures	4
Total	62

hematomas with the post-traumatic group of depressed and compound fractures, meningocerebral cicatrices and focal cortical scars, and separating the abscesses into a third group of postinfectious cases (Table 1).

These two groups of post-traumatic and post-infectious cases, which are the subject of this paper, can be subdivided again on the basis of whether the lesion caused acute or chronic epilepsy. Thus the hematomas, depressed fractures and acute abscesses that may produce early seizures fall into the acute group, whereas healed abscesses and penetrating wounds of the brain that form contracting fibroglial scars may result in late chronic epilepsy.

## EPILEPSY AFTER CEREBRAL TRAUMA

### *Acute Epilepsy from Cerebral Compression*

**Intracranial hematomas.** Intracranial bleeding of all types may bring on convulsive seizures either by acute compression of the brain or by concomitant damage to the cortex.

Gamsu and Kubik,<sup>6</sup> who are making a special study of subarachnoid hemorrhage in this hospital, have found that bleeding of this type was accompanied by acute convulsions in 20 out of 118 cases. Fourteen patients died, with verification of ruptured congenital aneurysms in all 9 on whom post-mortem examination was permitted. It deserves passing comment that only 2 of these brains on sectioning showed direct injury to the cortex and underlying white matter by intracerebral extension of the clot. In this decade these patients were not submitted to arteriography or ventriculography, and none had intracranial explorations. It is diffi-

cult to explain why acute seizures develop when hemorrhage is limited to the subarachnoid space. On the other hand, when blood burrows into the cortex and underlying white matter their occurrence is easy to understand, both in the acute stage and also at later periods if the patient survives and the clot is replaced by a meningocortical scar or deeper cerebral cicatrix. The situation here is identical with that seen after drainage and healing of cerebral abscesses, which are generally recognized as a cause of chronic seizures. At present we have a patient under observation in whom a large subcortical hematoma has been effectively evacuated and the bleeding point in the anterior cerebral artery ligated at another clinic.\* Despite this brilliant diagnosis and life-saving surgical treatment, the delayed appearance of chronic epilepsy may necessitate another surgical intervention.

Focal seizures are a frequent warning signal of the development of a postoperative clot, having been present in 4 out of 12 cases that required secondary re-elevation of the bone flap for postoperative bleeding. These seizures are generally minor ones, producing fine twitching movements of the opposite side of the face, with rare extension to other areas. Prompt surgical exploration, with evacuation of the clot and control of any bleeding that is still present, has invariably resulted in early cessation of the seizures in both the postoperative hematomas and the post-traumatic variety discussed below.

Intracranial hematomas such as clots that occur after tearing of the middle meningeal artery may cause convulsive seizures. During this decade we have encountered this complication in only 1 of 9 cases of typical acute epidural hemorrhage following temporoparietal fractures with injury to the middle meningeal artery.

Subdural hematomas of venous origin, which expand much more slowly than the arterial extradural variety, may also lead to seizures. Kunkel and Dandy<sup>7</sup> reported attacks in 12.7 per cent of 48 cases, but Elvidge<sup>8</sup> concludes that this is a rare complication of subdural bleeding unless there is concomitant cortical injury. Our findings support those of Kunkel and Dandy.<sup>7</sup> Among 120 patients in whom such clots were diagnosed and evacuated, transitory seizures were observed in 10†. In 6 out of 7 cases in which there was no other obvious damage to the brain the seizures stopped and have not recurred. In the single exception there were only two attacks in the next two and a half years. In a case of closed head injury that had occurred eleven years previously, drainage of a large subdural hygroma has resulted in great improvement, so that the patient is able to

\*This patient a relative of one of us was referred to Dr. J. L. Poppen.

†Three other subdural hematomas accompanied by convulsions have been drained during this decade. As it has been possible to keep the patients under observation for only a few months their freedom from epilepsy cannot be regarded as permanent.

visual aura (a small black bird hovering in the right upper visual field) and major Jacksonian convulsions lateralized to the right. X-ray films showed the 22 caliber bullet at the tip of the temporal lobe with the ventricle dilated and drawn toward the scar. The patient had a very slight aphasia and reduction of the right visual field. At the time of exploration (September 5, 1940) the track of the bullet was disclosed wiping out the sylvian fissure (Fig 2). Stimulation at marker No 4 set off a mild facial seizure with twitching of the corner of the mouth, followed for about 5 minutes by partial aphasia. We were therefore forced to content ourselves with resecting the posterior portion of the scar, where the bullet had entered, and a deeper area at the tip of the left temporal lobe. The bullet, embedded in bone, was not removed. With the exception of four major seizures, the last in 1943 after the patient had omitted dilantin, he has had only rare minor spells. In these he has to stop work in a shoe factory for a few minutes on account of a sense

methods of obtaining electrocorticograms by means of the sterile electrode holders and by mapping the spread of the after-discharge following electrical induction of a subclinical seizure (Walker et al <sup>4, 5</sup>), it is possible to excise small active foci of irritable

Electrical stimulation at the markers caused flexion of the fingers of the right hand (No 1), contraction of forearm flexors (No 2), sensation at the right knee (No 3) and a brief convulsion limited to the face starting with movements of the corner of the mouth on the right side (No 4)

of confusion, but can talk with difficulty. At the time of his last visit, 4 1/4 years after operation, he had had no seizures for 6 months.

In this decade, although accurate mapping of the motor strip could be carried out under local anesthesia with the thyratron stimulator, the method of delimiting epileptogenic areas by inducing clinical seizures through electrical stimulation was at best a crude one. At present, with the more refined

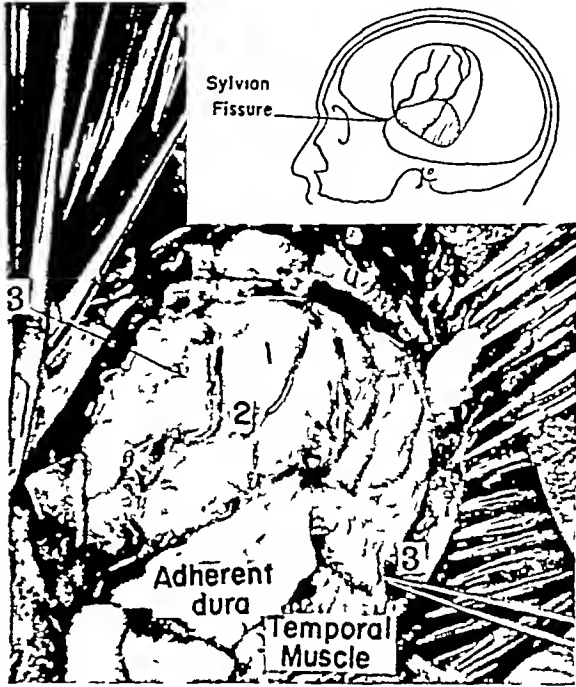

FIGURE 3 Adherent Meningocortical Cicatrix in Dominant Temporal Lobe, Which Gave Rise to Jacksonian Seizures Starting with an Auditory Aura. Electrical stimulation at Marker No 2 caused a low prolonged cry, followed by flexion of arm muscles and then a generalized convulsion. Areas of abnormal-appearing cortex and pia arachnoid (Marker No 3).

cortex at the edge of large scars even in the most important areas of the brain. Considering the difficulties of accurate localization of epileptogenic foci during this period, the complete eradication or pronounced amelioration of seizures in 14 out of 28 patients has been most encouraging.

Mere freeing up of adhesions in a meningocortical cicatrix, which was all that could be undertaken when the epileptogenic focus lay in vital speech or motor areas, was at best an unsatisfactory procedure. At present exploration can be carried farther by analysis of the cortical electrogram, whereby small epileptogenic foci can often be localized at the edge of the scar by their emission of abnormal electrical waves and excised without serious loss of function. In addition, dural repair with fibrin film

The circumscribed lesions listed above may be classified further as examples of meningocerebral cicatrices or focal lesions of the cortex with more or less involvement of the underlying brain. Air studies, which frequently revealed pronounced distortion of the underlying ventricle, showed that the pathologic process was usually a deep one, with gliosis and atrophy extending into the white matter.

In all these cases every effort had been made to control the frequency and severity of seizures by

Results following exploratory craniotomy in 28 cases of traumatic epilepsy are summarized in Table 2. In these the trauma was traced back to birth or infancy in 9. In the 19 patients in whom it occurred in later childhood or adult life, 10 had suffered depressed or compound fractures, 7 closed head injuries (2 of whom had complicating subdural hematomas that had been previously evacuated), and 1 a focal scar, the exact cause of which could not be determined. The last is included with

\*Adhesions in this case were the residua of a previously drained subdural hematoma — small quantities of yellow fluid trapped in the subdural space with additional lakes in the subarachnoid.

†Re-exploration has recently been carried out with localization of an epileptogenic focus by the electrocorticogram. Excision has been followed by early improvement. Again no definite cortical scar was seen.

anticonvulsant drugs and general medical treatment. Operation was advised only in patients who failed to improve and in whom there was definite evidence of focal scarring shown by the aura and clinical manifestations of the seizure, neurologic examination, electroencephalogram (in the latter part of the series) and air studies.

**Post-traumatic epilepsy.** Exploratory craniotomy was performed in 37 patients after old or recent injury to the brain. Of these, 28 have been under observation for prolonged periods and are suitable for this study. It is important to remember that the source of the epileptic discharge is never within the cicatrix itself, but at some point in the transition zone between the completely scarred area and normal brain. Although the cortex at this point may not appear grossly abnormal, the nerve cells are distorted and compressed by a fine network of fibroglial tissue.<sup>2</sup> It is impossible to locate the epileptogenic focus in the periphery of one of these scars by inspection, and the best method available, prior to the recent development of electrocorticography, was locating the area from which seizures could be induced by the thyratron stimulator with minimal current. In the smaller scars situated in relatively silent areas, the entire area was excised with a small amount of surrounding cortex.

the cases of traumatic origin for want of a better classification. In another the cicatrix was due to a previous cortical resection in the premotor area for Parkinsonian tremor. With a single exception, follow-up studies have been carried over a period of eighteen months to nine years in all cases. The final status of these patients on whom our evaluation of the results is based is presented in Table 3.

Of 11 patients with foci that were small or so favorably situated that the entire visible cortical cicatrix or meningocortical scar could be excised, 6 have never had another seizure, and 2 others have had such a reduction in frequency and severity of attacks that they are able to work and to lead normal lives. The remaining 3 have shown definite, maintained improvement in the severity and frequency of the seizures, so that with the aid of medication all have been able to lead active lives.

In 7 patients with partial excision of the cerebral lesion, 4 failed to obtain any notable improvement. In the remaining 3, however, the results were very definitely encouraging. The following case report is of interest because the site and extent of the scar presented a particularly difficult problem.

A 21-year-old man had had a previous debridement of a gunshot wound of the left temple at this hospital in 1933. Epilepsy began 7 years later, characterized by an elaborate

visual aura (a small black bird hovering in the right upper visual field) and major Jacksonian convulsions lateralized to the right. X-ray films showed the .22 caliber bullet at the tip of the temporal lobe with the ventricle dilated and drawn toward the scar. The patient had a very slight aphasia and reduction of the right visual field. At the time of exploration (September 5, 1940) the track of the bullet was disclosed wiping out the sylvian fissure (Fig 2). Stimulation at marker No 4 set off a mild facial seizure with twitching of the corner of the mouth, followed for about 5 minutes by partial aphasia. We were therefore forced to content ourselves with resecting the posterior portion of the scar, where the bullet had entered, and a deeper area at the tip of the left temporal lobe. The bullet, embedded in bone, was not removed. With the exception of four major seizures, the last in 1943 after the patient had omitted dilantin, he has had only rare minor spells. In these he has to stop work in a shoe factory for a few minutes on account of a sense

methods of obtaining electrocorticograms by means of the sterile electrode holders and by mapping the spread of the after-discharge following electrical induction of a subclinical seizure (Walker et al<sup>4,5</sup>), it is possible to excise small active foci of irritable

cortex at the edge of large scars even in the most important areas of the brain. Considering the difficulties of accurate localization of epileptogenic foci during this period, the complete eradication or pronounced amelioration of seizures in 14 out of 28 patients has been most encouraging.

Mere freeing up of adhesions in a meningocortical cicatrix, which was all that could be undertaken when the epileptogenic focus lay in vital speech or motor areas, was at best an unsatisfactory procedure. At present exploration can be carried farther by analysis of the cortical electrogram, whereby small epileptogenic foci can often be localized at the edge of the scar by their emission of abnormal electrical waves and excised without serious loss of function. In addition, dural repair with fibrin film

and reconstruction of cranial defects with acrylic resin plates\* can now be used to reduce the reformation of meningeal adhesions that distort the vasogial framework of the adjacent cortex. Penfield and Erickson<sup>3</sup> have stated that mere lysis of adhesions cannot be expected to give any significant improvement, and with this we are in general agreement. However, it is remarkable that a patient whose operation was limited to the release of yellow subdural fluid left from the previous drainage of a

of the high-protein-containing fluid and lysis of adhesions the former had no seizures and was working hard over a four-year period, whereas the latter has been unimproved. The difficulties encountered in the remaining case, in which dense adhesions bound the dura down to the cortex in Broca's area, are illustrated by the following report:

A 28-year-old man, after a compound depressed fracture in the left temple, developed epilepsy within 1 month. He had Jacksonian seizures for 3 years, beginning with an

TABLE 3 Postoperative Follow-up Data on 28 Patients with Chronic Traumatic Epilepsy Selected for Statistical Analysis.

CASE NO.	SEX	AGE yr	POSTOPERATIVE COURSE	ANTICONVULSANT MEDICATION	FOLLOW UP PERIOD
Excision of scar with depressed or compound fracture					
18	M	24	No attacks except immediately after operation	No	12 yr
28	M	12	Patient symptom free and leading normal life	No	2½ yr
21	M	25	Patient working sporadically; no seizures but some character change reported	?	2½ yr
15	M	31	Patient working	No	7½ mo
12	F	9	Patient attending school; seizures only when medication is omitted	Yes	3 yr
16	F	31	Patient engaged in housework; 2 or 3 seizures yearly, but none for last 6 mo	Yes	3½ yr
1	M	26	Patient working hard but has had seizures at rare intervals and one period requiring hospital admission	Yes	2 yr
Partial excision of scar with depressed or compound fracture					
26	M	21	No seizures on dilantin for past 6 mo	Yes	4 yr
13	M	15	No change; patient in corrective institution	Yes	4½ yr
Lysis of adhesions with depressed or compound fracture					
22	M	28	No change in frequency or severity of seizures	Yes	8½ yr
Excision of scar with closed head injury					
20	M	33	No seizures, patient works as athletic coach	?	4 yr
Lysis of adhesions with closed head injury					
4	M	20	No seizures, patient engaged in heavy construction work	?	4 yr
14	M	14	Headache and 2 seizures; patient in school and is ardent athlete	?	2 yr
17	M	19	Patient working and looks well but had one bout of status epilepticus (his statements may not be reliable)	No	11 yr
24	M	26	No change in epileptic status	Yes	6½ yr
27	M	40	No seizures; patient director of a War Production Board during war	?	10½ yr
Exploration only for scar with closed head injury					
6	M	18	Definite reduction in frequency of seizures; patient able to work as farmer but has series of seizures occasionally	Yes	6 yr
Partial excision of scar due to previous surgery					
3	M	25	No change in seizure pattern; recent re-exploration	Yes	6 yr
Excision of scar of undetermined cause					
25	M	38	Patient does regular office work; seizures reduced to less than half their former frequency	Yes	2 yr
Excision after birth injury					
23	M	15	Patient works for General Electric Company; two spells in last 6 mo	Yes	6½ yr
5	M	12	Patient goes to school and leads normal life; no seizures.	No	5½ yr
Partial excision after birth injury					
10	M	11	About 2 seizures per month but less frequent and severe than preoperatively; patient keeps up at school	Yes	1½ yr
19	M	19	Only 1 seizure per year; patient engaged in active work	Yes	7½ yr
9	M	3	Patient in state school and has series of convulsions about once a year; hemiplegia has increased	Yes	9 yr
11	F	20	Seizures continue with progressive mental deterioration	Yes	7 yr
Diffuse atrophy due to birth injury; no focus excised					
8	M	8	No change in seizures	Yes	2 mo.
2	M	19	No change in seizures	Yes	9 yr
Negative exploration after birth injury					
7	M	25	No change in seizures; second exploration recently has localized resectable focus	Yes	8 yr

hematoma, with evacuation of further lakes under the arachnoid, has had complete freedom from seizures over a period of nine years. During the war he became head of the War Production Board in a large industrial city. Two other patients have been operated upon with the finding of trapped lakes of yellow fluid in the subdural space and accompanying atrophy of the underlying cortex following old closed head injury (Tables 2 and 3). After release

auditory aura, difficulty in speech and numbness and tingling of the right arm and leg, followed by loss of consciousness and biting of the tongue. At the time he left the New Haven Hospital, where the cerebral laceration was debrided and a hematoma evacuated by Dr. William J. German, he had difficulty in reading, writing and speaking, but this had improved so that on his second hospital admission here he had difficulty only when excited or at the onset of an attack. Neurologic examination was not remarkable except for slight residual aphasia. An electroencephalogram demonstrated slow waves in the left motor area, and a pneumoencephalogram showed the ventricle on the left to be slightly dilated and drawn to this side. The situation found at operation on October 19, 1948, is shown in Figure 3. The dense adhesions between the dura and cortex were divided and some areas of yellow, softened cortex in the temporal

\*Cranioplasty with plates of acrylic resin is preferable to the standard method with tantalum in epileptic patients since this material permits subsequent pneumograms to be made if continued seizures necessitate further investigation.

lobe sucked away, but at that time it was impossible to proceed farther for fear of producing a profound aphasia. There has been no change in the number or severity of the seizures.

Technical advances developed during the war have made surgical cure of cases of this sort possible. This patient will soon be readmitted, and it is planned again to free up the meningocerebral adhesions. With the cortical electrodes and direct recording of the brain waves it may then be possible to locate and excise a small epileptogenic focus at the periphery of the extensive scar without interfering with the speech areas of the dominant temporal lobe. The dura will be repaired with fibrin film to prevent reformation of a contracting meningocerebral scar, and the defect in the skull closed with an x-ray-transparent plate of acrylic resin.

Of 5 patients submitted to exploratory craniotomy, in whom diffuse areas of cortical atrophy were exposed without any clear-cut local lesion that could be excised, only 1 (Table 3, Case 6) maintained a lasting improvement of minor degree. He is able to work as a farmer, but has occasional recurrences of seizures. In several other cases, however, there was temporary improvement that might have been considered significant if follow-up observations had not been carried over prolonged periods. Brief postoperative observation in the past has often given rise to misleading conclusions, since any nonspecific operation, such as sympathectomy or even resection of the colon, has led to a temporary reduction of seizures.

When the presence of an irritable focus is well established by characteristic Jacksonian seizures and persistent abnormality in the electroencephalogram, the failure to find an epileptogenic lesion should lead to a most careful search for an underlying neoplasm. We have failed to locate such tumors in 3 cases. Pneumoencephalograms in these patients did not suggest an expanding lesion, and 2 of them gave a definite history of previous cranial injury. After the bone flap had been turned down, no very convincing cortical lesion, but only a mild degree of diffuse cortical atrophy, was disclosed in 2 cases. In the third a pinkish area with increased vascularity was observed and excised, since it gave rise to seizures on electrical stimulation. Microscopical examination, however, failed to show either gliosis or tumor. All 3 patients were regarded by the operating surgeon as tumor suspects, and careful exploration was made by palpation and diagnostic puncture. No patient had lasting relief of seizures, and all failed to return for further observation. Subsequent investigation disclosed that the first died three years later after a period of aphasia followed by coma. The other 2 were reoperated upon at other neurosurgical centers, with the discovery of an oligodendroglioma and a fibrillary astrocytoma, respectively. We have had a number of similar experiences with epileptic pa-

tients who had had a previous exploration at other clinics. Since epilepsy is frequently the first symptom of an underlying glioma or meningioma, since the seizures may persist for years without causing any rise in intracranial pressure or neurologic signs and since the pneumogram may at first be perfectly normal,<sup>1</sup> it is most important to bear in mind the possibility of a subcortical tumor even in a

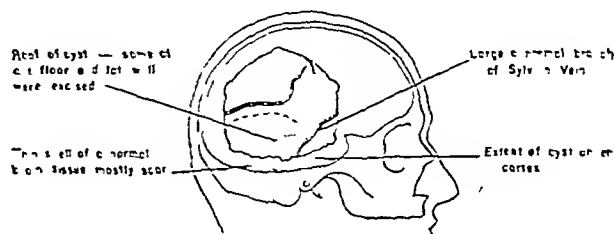

FIGURE 4 Large Porencephalic Cyst in a Young Woman with a Ten-Year History of Epilepsy Accompanied by a Mild Left Hemiparesis and a Homonymous Field Defect (Seizures Began with a Sensory Aura, Followed by Turning of the Eyes and Head to the Left and Contraction of the Left Facial Muscles)

Marker No 6 is on the motor strip. Electrical stimulation at the other markers induced no seizure or other response.

patient whose seizures have followed a definite cranial injury.

The statistics presented above give a good idea of the relative value of complete versus inadequate eradication of epileptogenic foci. After apparently complete excision good results were obtained in over half the patients, whereas failure to locate a circumscribed lesion in cases of diffuse atrophy was invariably followed by a continuation of the convulsive seizures. It is also of interest to break down the statistics in another way to show the results of surgery in seizures resulting from the more fre-

quent pathologic lesions that follow cerebral injury. These are presented in Table 2. From our experience with these cases we have come to the conclusion that surgical intervention can be undertaken with approximately equal chances of success in the various types of epileptogenic scars that follow trauma in the adult brain. In 11 of the 19 patients followed over adequate periods the results of surgical intervention were distinctly worth while. On the other hand, in the 9 cases in which epilepsy followed a history of birth injury or damage to the brain in early infancy, only 4 patients obtained lasting reduction in the frequency and severity of seizures. This is because injury to the rapidly developing brain of an infant is likely to produce diffuse areas of atrophy or large porencephalic cysts of the type illustrated in Figure 4. None of the patients with diffuse atrophy improved, since no focal areas could be excised. Of the 4 cases of porencephalic cysts treated by partial excision of the cyst wall and glial scar at the periphery, the results in 2 are not encouraging. Case 5, a twelve-year-old boy whose spells began at the age of three and averaged a major seizure daily, has had complete freedom for a period of five and three-quarters years. Neurologic examination is negative, and the electroencephalogram has returned to an almost normal pattern. He requires no medication and has been able to catch up with his proper grade in school. The other (Case 19), whose seizures began at the age of twelve, was operated on at the age of nineteen, and a large cystic lesion was found in the postcentral cortex. This led down to the lateral ventricle, and much of its anterior margin could not be excised owing to the proximity of the motor arm area. During the ensuing eight years he has been able to work steadily as a welder, with only occasional seizures, which disappear altogether when he remains on a careful regime with adequate anticonvulsant medication. The other patients received no benefit, and the one whose lesion is shown in Figure 4 has deteriorated mentally to the point where she should soon be committed to an institution. When birth injury results in a small cortical scar or focal atrophy (microgyria) the results of excision can be just as good as those in the adult group. Judging from Penfield and Erickson's<sup>3</sup> much larger series, it seems fair to conclude that in our few cases there was an unduly small proportion of eradicable lesions. Even in this least promising group the results following resection of a local scar or atrophied convulsion should be distinctly worth while, provided there is not coexistent extensive atrophy of the brain.

*Epilepsy after cortical excision.* Epilepsy as a result of cortical excision has rarely been reported. That it may follow operations for brain tumor is a possibility, for seizures sometimes occur for the first time after the apparent total resection of meningiomas and certain circumscribed gliomas.<sup>1</sup>

Under these circumstances, however, the epileptic disturbance has been ascribed to the tumor rather than to the operative scar. Be that as it may, this unfortunate complication does follow cases of cortical resection undertaken for the control of abnormal movements and uncontrollable tremor as seen in Parkinsonism and athetosis. Here, even with the most perfect surgical technic, a cicatrix is produced close to the motor strip, in an area that is known to produce the greatest risk of seizures. In view of the frequent enthusiastic publications of Klemme<sup>12</sup> the risk of such a complication is important to bear in mind. Postoperative epilepsy, which is also a complication of prefrontal leukotomy, has been reported by Freeman and Watts<sup>13</sup> in 4 per cent of their cases. We have encountered 2 cases in which epilepsy developed after cortical resection for tremor and have heard reports of others. In our personal cases there was a history suggestive of minor seizures before operation, the preoperative electroencephalogram was slightly abnormal, and seizures were induced in the course of mapping out the motor area prior to the cortical resection. An experience of this sort should certainly warn the surgeon against resecting the premotor area. In one of these unfortunate cases (Case 3, Table 3) we have twice reoperated and removed the more excitable portion of the scar. There was little improvement after the first operation, but after the second, in which the cortical electrode holder was used, the early results are promising.

#### EPILEPSY AFTER CEREBRAL INFECTION

An expanding cerebral abscess may produce acute epilepsy through cortical compression and added irritation from the zone of thrombosis and encephalitis at its frontier. In a series of 72 cases of supratentorial pyogenic abscess secondary to inflammation in the sinuses, mastoids or lungs, 9 were accompanied by acute convulsive seizures. These had a most serious prognostic import, since only 2 patients survived and these continued to have spells after healing.

In addition to the early seizures seen in the acute inflammatory stage of brain abscess discussed above, the condition has developed chronically in 11 patients with healed lesions, not all of whom were treated initially in this hospital. In only 4 of these was surgical intervention indicated and undertaken. In 1 the parasagittal postcentral scar from which an abscess had been radically enucleated resulted in seizures because of local atrophy and the formation of a porencephalic cyst communicating with the lateral ventricle. Excision of the cyst has given a good seven-year result, marred only by three convulsions at the time of childbirth. Two of the other patients operated upon had large scars binding the frontal lobe to the posterior wall of the diseased sinus. In both the scars were excised with

a narrow margin of normal-appearing brain. One, during a period of nine years, has averaged about one seizure a year, with none in the last three years. The other, whose extensive cicatrix is illustrated in Figure 5, has had no seizures in five years and has been able to work full time as a medical secretary. In a fourth case, in which an epidural abscess developed after a fracture that involved the frontal sinus, radical excision of the underlying cicatrix in the frontal lobe has given a fairly good result. Four and a half years afterward this patient was married and leading a normal life. Although she had rare seizures when off medication, these were controlled effectively by dilantin.

#### SUMMARY AND CONCLUSIONS

Of this series of 80 patients explored for acute or chronic epilepsy following cerebral trauma and infection, 18 have been eliminated from analysis because of inadequate periods of observation or other reasons. Of the remaining 62 in whom prolonged follow-up observations are available, definite lesions were visualized at operation in all but 1. In the acute variety the seizures were associated with intracranial clots in 15, depressed fractures in 6 and abscesses in 9. The results after cortical decompression in the hematomas and depressed fractures were uniformly good, except in cases in which there was a superimposed contusion of the underlying brain. When convulsions accompany a subdural or subcortical abscess the prognosis is extremely poor, both for the life of the patient and for relief of the seizures.

Late chronic epilepsy is caused by fibroglial scars producing meningeocerebral adhesions or cicatrices of the cortex and underlying white matter. When these lesions are small and situated in relatively silent areas of the brain, the results of excision are good. If the cicatrix is a large one, or situated in vital speech and motor areas, total extirpation is out of the question. In such cases it may be possible to find a small focus responsible for the epileptic discharge. This never comes from the scar itself, but from partially damaged cortex at its periphery. In the decade from 1935 to 1944, when the surgeon had to depend on localizing the epileptogenic focus by the crude method of inducing gross seizures by electrical stimulation of the exposed cortex, our follow-up statistics show that in a series of 28 patients explored for chronic epilepsy of traumatic origin, 24 have had focal lesions suitable for surgical attack. Of these, 8 have had complete freedom from seizures for periods up to nine years. Another 6 have had a great reduction in both the frequency and the severity of their attacks, some with only an occasional seizure in the early months followed by long periods of complete freedom. All these patients are able to lead active and relatively normal lives, although they have been urged to

continue taking anticonvulsant drugs. Five others have had sufficient improvement to be able to lead useful lives, whereas the remainder, including those in whom no operable lesion was found, received little or no benefit.

Three patients in whom cortical atrophy was at first held responsible for seizures later developed characteristic signs of brain tumor. Two of these had a definite history of previous cranial injury.

Postoperative results of excision of cortical scars after healing of intracranial abscesses were all that

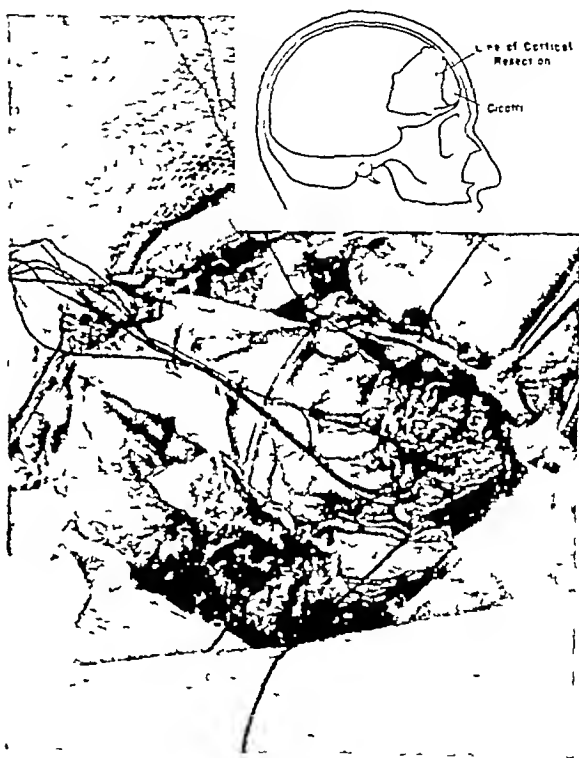

FIGURE 5 Cortical Scar at Tip of Right Frontal Lobe, Resulting from Frontal Sinusitis and Osteomyelitis, Complicated by Brain Abscess Three Years Previously.

*Jacksonian epilepsy, characterized by turning of head and eyes to the left, with clonic movements of the left side, followed by generalized seizures, had been present for a year.*

could be wished for in 1 case and very satisfactory in the other 3.

Recently developed means of delimiting the circumscribed epileptogenic focus with much greater accuracy by the use of direct cortical brain waves at operation and the production and mapping of subclinical seizures promise far better results. This method offers special hope in the extensive scars that are too large for total resection and in those situated in the vital speech and motor areas of the brain. As results obtained by this new technic cannot be evaluated for a period of years, it has

seemed worth while to present this statistical review of end results achieved in the preliminary period of the surgical attack on epilepsy

## AGGRESSIVE BEHAVIOR — ITS PSYCHIATRIC AND PHYSIOLOGIC ASPECTS, ESPECIALLY IN COMBAT VETERANS\*

LEO ALEXANDER, M D †

BOSTON

**I**MIMPULSIVE aggressive behavior is more frequent among the cases encountered in military psychiatric practice, especially in or near combat zones, than in civilian practice exclusive of cases appearing in combat veterans

While serving with an overseas general hospital as chief of the neuropsychiatric section, I was impressed with the number of cases in which aggressive behavior presented the predominant symptoms and cause for admission or consultation. In the study of these cases from the psychiatric as well as from the neurophysiologic point of view, the courtesy and co-operation of Dr Denis Hill made it possible for the patients to be taken for electroencephalographic examination to the laboratory under his charge at the Sutton Emergency Hospital. In going over the list of these patients and the causes for their admission, I find the following comments

"Irresistible urge to drive and wreck jeeps while intoxicated" "Brutal attack on a woman while intoxicated — had cerebral concussion when enemy shell exploded five feet from him" "Aggressive behavior while intoxicated with beer, covered by retrograde amnesia — knifed a fellow soldier who was his best friend in his organization" "Impulsive aggressiveness under alcohol, pathologic intoxication, with amnesia for entire episode" (The case of this officer, a grounded flier, will be reviewed in

detail later) "Assault and attack on a colonel while intoxicated, one previous episode of assault against a woman while intoxicated, for which he had been punished" (The differential diagnostic question was epileptic equivalent or alcoholic cerebral degeneration) "Attempt to rape 12 women, 8 of them in one afternoon within one hour" "Insults and threats against his hutmates on the part of a staff sergeant who had consumed a not inordinately large amount of alcohol" (This patient was disarmed and put to bed and had no recollection of the episode on the following day)

It was remarkable that with the exception of the last patient, in whom six-per-second low-voltage potentials were found in transverse leads over the parietal areas, such as were found in aggressive personalities of this type by Hill and Watterson,<sup>1</sup> all the patients showed completely normal cerebral electroactivity, a fact that contrasts somewhat with civilian experience. Civilian patients with brutal, impulsive, aggressive outbursts frequently show the type of "psychopathic" abnormality mentioned above, with instability of the cerebral electroactivity to physicochemical stress. It is rather surprising to find that persons with similar outbursts in military life, especially in combat personnel, tended to show these abnormalities only rarely — in only 1 case among my wartime patients. The explanation of this is probably that such outbursts of behavior are, of course, the combined results of biologic abnormality and emotional stress. If the stress is slight, the biologic abnormality has to be great to cause the abnormal behavior

\*From the Division of Psychiatric Research, Boston State Hospital, and the Department of Psychiatry, Tufts College Medical School

†Instructor in psychiatry Tufts College Medical School, associate director of psychiatric research, Boston State Hospital, consulting psychiatrist and neurologist, Washington Hospital, assistant neurologist, Beth Israel Hospital, attending neuropsychiatrist, Veterans Administration Hospital, West Roxbury, Massachusetts.

When the stress is great, little or no biologic abnormality is necessary to produce the same result.

Another important fact was that, without exception, alcohol played a part in bringing out the abnormal behavior. In a few cases, especially in combat personnel under stress, remarkably slight amounts of alcohol sufficed to bring out the aggressive behavior reaction, but ingestion of alcohol precipitated the outburst in all. An exception was a recent case, in which the disturbance of cortical inhibitory centers, essential for bringing out this behavior pattern and usually produced by alcohol, was accomplished by another physiologic interference with cortical activity. This case is discussed below.

The types of aggressive behavior that presented themselves could be divided into the following groups:

Aggressive behavior that is directed against a specific person who incurs the patient's hostility, which is displaced, however, against another, either a similar person or a symbol of that person. An example of this type is that of a sergeant in the Air Force who received a letter from his wife telling him that since his absence overseas she had become interested in another man. He brooded over this for some time and finally wrote to his wife that he would be willing to give her a divorce. On his next day off he went to a pub with friends. After drinking not more than his usual amount of liquor, he went out into the street, walked up to a civilian couple, kicked the man and started choking the girl. Later, he had no recollection of this episode at all. His electroencephalograms were normal. He spoke of the marked resentment he felt against his wife and it was quite obvious that in that setting he committed an act symbolic of what he wanted to do to his wife. He had had a fine military record before this incident, the only predisposing factor in his background was that his father was an alcoholic who had finally lost his home and his financial and social standing because of his drinking.

Aggressive behavior in terms of projection occurred particularly in combat personnel who had had some anxiety regarding combat and who had been temporarily or permanently released from combat duty. A rather common example of this was the flier grounded after a number of combat missions because of his increasing emotional tension. Such a man, after drinking for a while at the club, sometimes accosted another man grounded for similar reasons, abusing him verbally, pulled his gun and tried to shoot him. Here, his aggression, generated against himself, was projected and directed against another person in a similar position — especially in a setting that included drinking.

During aggressive behavior resulting when a large amount of aggressive hostility is directed indiscriminately against any and all people, the patient's consciousness is usually clouded. He is often described as having been rather subdued and not in as good spirits as usual prior to the outburst. An example is afforded by the following case:

A flier (second lieutenant), who had been under considerable combat-flying stress, was grounded because of tension and became self-critical, self-reproachful and anxious. In this state, he went to a neighboring town one evening and bought a quart of whisky to share with friends at a private club. He did not drink more than usual, he was a man who could usually handle his liquor well. He had in a somewhat subdued and tense mood consumed his usual amount of alcohol when he suddenly rose, called bystanders "Yellow, dirty Germans" and then literally tore the club apart. He was in a state of wild excitation. It took several men to restrain him, and even then he tore the buttons off the uniform of a flight surgeon who had been called to the scene. The next day he was quite subdued, tense and anxious — not on account of the incident, but just in general.

The British police have a very thorough way of taking down statements practically verbatim, as they did in this case. When I read the record of the exclamations and statements that this officer had made during the fracas, I found them to be strikingly similar to the expressions that another officer had poured forth under therapeutic abreaction by sodium pentothal, the latter officer was likewise a combat aviator, who had had two crash landings as well as other combat stress and who had become very tense. During an abreaction treatment with sodium pentothal he had suddenly given vent to a violent, aggressive emotional reaction, using almost exactly the same violent expressions as the lieutenant had used on the dance floor of the club. A comparison of the practically identical stenographic statements led to the conclusion that this lieutenant had inadvertently abreacted himself with the alcohol, which had acted on the cortex, or the outer cortical layers, in such a manner as to allow the tension and reactive aggression that had accumulated in the lower cerebral mechanisms to express themselves. The military court accepted my interpretation of the incident.

Regardless of what causes the cortical dysfunction — alcohol, sodium pentothal or any other cortical sedative or disorganizing agent — the accumulated excessive emotional pressures in the deeper centers of the brain frequently express themselves in that aggressive manner. Aggression is the natural consequence of anxiety. And in men who go through their daily combat routine, with its inevitable anxieties, there is an accumulation of aggressiveness that is bound to explode under conditions of depression of the higher cortical functions. The higher levels of the cortex, the inhibitory

ing organ, restrain the lower cortical spheres and the basal ganglions, which are the main outlets for aggression on a primitive physiologic level and probably also on a higher psychologic plane. Anything that disturbs the higher discriminating functions of the cortex will cause a release in the more primitive mechanisms, including those of the sub-cortex, this release in no way depends on what incapacitates the cortex. In epilepsy, for example, a great deal of abnormal cortical electroactivity is present, which may indicate a degree of cortical disturbance sufficient to interfere permanently or temporarily with the higher discriminating functions of the cortex. In patients with focal brain lesions there is usually only focal abnormal cortical electroactivity. The ingestion of alcohol may cause the abnormality to spread from its focal point to envelop the entire cortex, normally a source of controlling influence, and the entire cortex may become temporarily worthless. In the presence of emotional disturbance, especially anxiety and tension, the disorganization of cortical discriminating functions by alcohol alone is sometimes sufficient to release aggressive outbursts. In both of the two latter instances, one speaks of "pathologic intoxication." In "normal intoxication," there is a proportionate inhibition of cortical discriminating functions and of activity, including aggressive activity.<sup>2</sup>

I have encountered interesting cases of eruption of aggression in veterans after their return to civilian life. One of the surprising features in these cases is the understanding sympathy and tolerance of the patient's relatives. An example is provided by the following case of a husband who cut his wife's throat with a razor, for which act he is now serving a sentence at the state prison colony. His wife holds no grudge against him but considers the assault a symptom of his emotional illness—certainly a most enlightened view on the part of the victim. This view was not shared by the court.

The patient had been an ammunition loader in the Pacific Theater and had performed his duties well until the time when he was unloading an ammunition ship in the Aleutian Islands and had to get off the ship in a hurry because of an approaching storm. He slipped and fell 25 feet to a barge below. He was unconscious for 10 minutes, bled from the nose and injured his left hand. Shortly after this episode he developed nervous excitability and headaches, which soon became disabling, he was sent home and discharged for neurosis.

One evening when he dined out with his wife he consumed three mugs of beer and a "shot" of whisky. His manner was calm, and they had no arguments. On returning home his wife lay down for a nap, and he covered her with a blanket. About ½ hour later she was suddenly awakened by a sharp pain. Blood was flowing from a long, deep cut on the right side of her neck (a 4-inch scar remained as evidence when I saw her 8 months after the incident). Her husband was standing over her, staring at her, a razor blade in his hand. When she asked him what he had done he did not answer but went to the closet, got a clean towel and wrapped it around her neck to check the bleeding. Then he ran out and gave himself up at the police station. All the patient remembered about the incident, however, was covering his wife with a blanket when she first lay down, and the next thing he knew "she was lying there bleeding, and I ran out of the

house for help." He was observed at the metropolitan state hospital and was considered legally sane but suffering from "psychoneurosis." He was tried and convicted for assault.

When I examined him at the state prison colony I found a man of small stature, extraordinarily tense, anxious and jittery, as well as definitely depressed. His sleep was still haunted by nightmares, he frequently dreamed of loading an ammunition ship, of somebody yelling, "Get off quick!" and then of awakening from the explosion, which usually turned out to be a slammed door or a similar noise. However, he was free of guilt feelings about his deed "because I did not know what I was doing at the time—I just pleaded guilty because the lawyer told me to." He did think that he had made other mistakes. He felt he should have stayed in the Army, and had a stronger guilt feeling about that than about attacking his wife.

Neurologic examination revealed normal findings—especially, normal Achilles reflexes and vibration sense. My diagnosis was "psychoneurosis, anxiety-tension state, severe." The recent history suggested that marked unconscious, repressed aggressiveness had erupted under cortical sedation by a small amount of alcoholic beverages, producing a state of pathologic intoxication.

In the cases discussed above, cortical dysfunction was always affected by alcohol. Hill<sup>3,4</sup> found that in cases in which there was a focal abnormal cortical electroactivity, ingestion of alcohol—especially beer—made this abnormal electroactivity spread all over the cortex. Hill<sup>3,4</sup> has likewise shown that with ingestion of a similar amount of water, especially in cold weather, which facilitates hydration of tissues, the same result could be obtained. In a case of matricide described by Hill and Sargent<sup>6</sup> aggressive behavior associated with abnormal cerebral electroactivity resulted from the combined effects of low blood sugar and hyperventilation incidental to a violent argument.

I was recently asked to examine a combat veteran who had committed an unreasonable aggressive act that was not in keeping with his personality or his situational needs. He had been under tension incidental to frustrating experiences after his return to civilian life—he had not succeeded in getting into the college of his choice, he had not obtained the job he wanted, and his girl had jilted him while he was overseas. About his state of mind after his return in January, 1946, he said, "I was unsettled. I wanted so much, but nothing was panning out. It wasn't what it was cracked up to be. A lot of things I didn't want to happen did happen." This case is reported in detail, as follows.

In March, 1946, this 21-year-old man started working 9 or 10 hours daily in a cold-storage plant at -10 to -15°F. When he left the plant after work, at first he was chilly for ½ hour and then became uncomfortably warm, and if he engaged in any exercise he "perspired to beat the band while my friends would be dry as a bone." This feeling usually subsided during the night.

One evening after coming home from work, he changed to his dungarees and field jacket, stuck an unloaded German Luger pistol into his belt (for which action he had no explanation) and then drove around for several hours and vaguely headed toward the home of the girl who had jilted him, but on the outskirts of the town he turned and drove back toward Ft. Devens and then to Littleton, where he stopped at a store for a package of cigarettes.

In reaching for his wallet in his back trouser pocket, he exposed the gun in his belt, and when he noticed that the storekeeper became frightened and panicky, he was surprised, for he had forgotten that the gun was there. "I did

not know exactly what to do, so right off I hacked away, pulled out the gun, and said, 'Give me the folding money'." The storekeeper gave him about \$20, which he put in his wallet, where he had \$47 of his own. Then he ran out and got away in his car, but a police car that was parked across the street chased and caught him. He surrendered, was very co-operative, helped the police look for the gun, which he had thrown from his car window, and in every way acted his usual polite self.

The robbery occurred at 10 00 p.m., after he had been driving around seemingly aimlessly for about 3 hours, he had left the cold-storage plant at about 5 30 p.m. He could give no motive for his crime. He had sufficient money of his own — about \$1000 in accumulated pay. His family, with whom he lived and with whom he was very congenial, were of good middle-class circumstances, owned their own home and car and were capable of supplying a college education for their children. The patient himself was a clean-cut, tall, personable young man who had been outstanding in high-school athletics and who on the basis of his intelligence, ability and personality assets, as well as on his own and his family's standing in the community, was entitled to look forward to a happy and successful development. He had never committed any criminal acts before, had been a good student in high school and had shown no signs of psychopathic instability in the past. There was no record of truancy or disorderliness. His war record was excellent, he had been a sergeant in the combat engineers attached to the Fourth

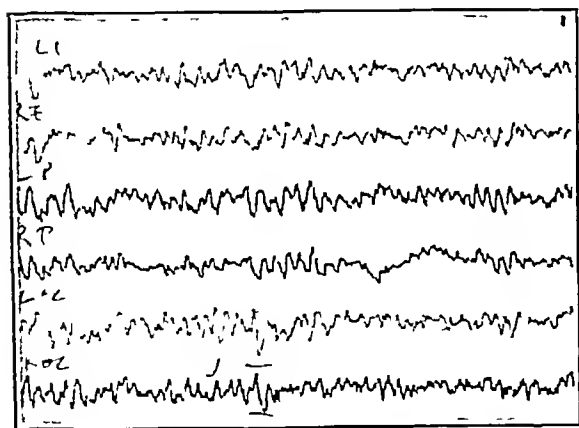

FIGURE 1 *Electroencephalogram Taken before Exposure to Cold*

The six leads are shown in the following order: left frontal, right frontal, left parietal, right parietal, left occipital and right occipital.

Armored Division, holding the rating of platoon sergeant from August, 1944, to January, 1946.

The history of his combat experience disclosed an incident of concussion with unconsciousness followed by a state of probable postconcussional confusion lasting 3 hours on February 4, 1945. This occurred during the battle of the crossing of the Saar River when an enemy shell struck a rocky ledge near his head. This instance of confusion was probably organic since it was not followed by any disturbance during subsequent combat activity (he afterwards participated in the Battle of the Rhine), as would inevitably have occurred had the incident been a neurotic fugue state.

Physical and neurologic examination revealed weakness of the right lower facial muscles, disturbance of abdominal reflexes on the right (the right upper being frequently absent), and the right middle and lower showing early exhaustibility), the right plantar reflex was abnormal, showing dorsiflexion of the great toe associated with outward rotation of the thigh and leg, and contraction of the fascia lata without fanning of the small toes.

Psychiatric examination demonstrated excellent general intelligence, and nonverbal testing by the Kohs block test revealed a mental age of 18½ years. However, his vocabulary level was reduced to one of 15½ years. A reading test revealed the presence of a moderate amount of dyslexia. There was some deterioration of the fund of knowledge, especially of history. All this contrasted with his high-school record of A's and B's in English and history. His blood pressure was elevated to 160/90.

Emotionally, the patient presented a superficially calm appearance, with a good deal of tension and resentment coming to the fore on psychiatric exploration.

Electroencephalographic examination, which was performed at Dr. Lennox's laboratory, revealed a focus of abnormal

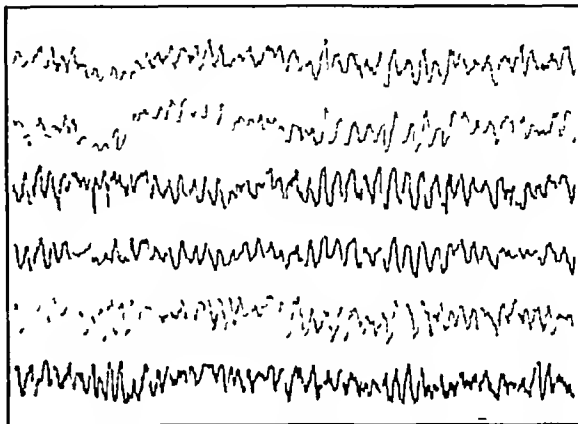

FIGURE 2 *Electroencephalogram Taken Four and a Half Hours after Exposure to Cold through Seven Hours with Alternating Periods of Twenty to Thirty Minutes Spent In and Outside a Cold-Storage Room with a Temperature between -10 and -15°F*

The six leads are shown in the same order as in Figure 1.

cerebral electroactivity with high-voltage, slow discharges at the rate of 5 or 6 per second, some of them square-topped, and diphasic slow spike discharges involving both occipital and parietal regions, more marked on the left (Fig. 1).

The aggressive outburst had occurred along the line of least resistance — namely, after the storekeeper had shown fear. In other words, the accumulated aggression, which was directed against those responsible for his frustrations and which the patient had held within him, had erupted toward the one man who had shown any fear of him.

From a study of the total personality it was believed that some organic factor was responsible for the patient's obtaining so much cortical release — that is, so much relaxation from his usually upheld behavioral standards in life, which are a function of his cortex. He was thoroughly questioned regarding whether or not he had been taking alcohol prior to the aggressive outburst. It was explained to him that whether he had been drinking or not would not make much difference from the medicolegal point of view, and the concept of pathologic intoxication was explained to him, but he steadfastly maintained he had had no liquor that day or even that week, that although he was not a teetotaler, he drank only on rare social occasions, that he did not derive particular pleasure from alcohol, and that he had throughout his military life abstained except on occasional passes and leaves because he felt that his position as platoon sergeant necessitated such abstinence.

The patient's actions on that day and his daily routine were reviewed. I then believed that it would be worth while investigating whether his occupational exposure to cold had any effect on his abnormal cerebral electroactivity. There is evidence<sup>6</sup> that the action of cold on cerebral electroactivity is similar to that of metrazol or eserine<sup>7</sup> and that in man shock from exposure to cold may be associated with tonic-clonic convulsions. These findings prompted Noell<sup>7</sup>

and others to advise against the use of analeptic stimulants such as metrazol and camphor for the treatment of shock from exposure to cold

It was arranged for the patient to return to the cold-storage plant, to spend a day there under conditions of observation with recording of his temperature, and to follow it by another electroencephalographic examination. It was found that the patient's temperature, which was 98°F at the start, fell to 97.2°F after 1 hour and to 97 after 3 hours' sojourn in the cold-storage room (in spite of 30-minute interruptions as usual in his work), it remained 97°F until he emerged at the end of the day, whereupon it began to rise gradually to 97.6°F 1 hour after emerging, to 98°F 2 hours after emerging, and then continued till it reached 99°F 4 hours after he emerged, staying at that level for an additional 5th hour and then gradually falling back to normal, his normal temperature of 98°F being reached 8 hours after emergence from the cold room.

The electroencephalogram was taken during the 5th hour after emergence—which was the approximate time at which he had committed the crime. It was found that the abnormal high-voltage activity had spread to all leads, in a way similar to what might have been expected from the effects of metrazol, eserine, alcohol or hydration (Fig. 2).

It was concluded that in this case heightened subcortical emotional aggressiveness was released because the cortical inhibitory centers had been disorganized, not by the effects of alcohol but by the effects of exposure to cold, which had permitted the abnormal electroactivity of a circumscribed traumatic focus to spread over the entire brain. No attempt was made to determine whether this

spread was actually the direct consequence of the cold or the consequence of the hyperthermic response elicited by the exposure to cold.

On the basis of these facts, which were presented to the Court, the patient was given a suspended sentence with a probationary period of two years.

### CONCLUSION

The study of aggressive behavior is a field of neuropsychiatry characterized by a remarkable degree of interplay of psychiatric and physiologic forces, the unraveling of which demands an understanding of the psychiatric as well as of the physiologic aspects of behavior.

## PRIMARY TERATOMATOUS CHORIONEPITHELIOMA OF THE OVARY\*

### Report of a Case

HOWARD M OLIVER, M D,† AND ELWOOD O HORNE, M D‡

WORCESTER, MASSACHUSETTS

**C**HORIONEPITHELIOMA of the ovary may arise from two fundamental sources—a pregnancy, uterine or ectopic, and a teratoma. It is our purpose to discuss only the latter, and to add a case to the literature.

Pick,<sup>1</sup> in 1904, described a nine-year-old girl whose abdomen revealed a teratoma of the ovary with mesodermal, entodermal and ectodermal components, and pure chorionepithelioma. Since then 12 other proved cases have been reported,<sup>2-13</sup> only 3 of which are reviewed in the American literature<sup>3, 12, 13</sup>. A few other cases must be eliminated because they followed pregnancies and may have represented metastases from uterine chorionepitheliomas that regressed spontaneously, were expelled with the placenta<sup>14-27</sup> or were removed by the curette.<sup>28</sup> A primary ovarian chorionepithelioma can be assumed with certainty only in a child.<sup>7</sup> Nine of the cases reported, including the one pre-

sented below, occurred in children before the age of puberty. Four of these (Table 1) presented evidence of precocious sexual development, and a fifth had uterine bleeding. In such cases a diagnosis can be made clinically since a positive pregnancy test (Aschheim-Zondek or Friedman)<sup>13</sup> diagnostic of teratomatous chorionepithelioma,<sup>13</sup> especially with dilute urine and spinal fluid. Other cases presented no typical symptoms, and 2 cases were diagnosed as appendicitis.<sup>4, 6</sup> Because of the age and the positive pregnancy test, the cases of Fasold,<sup>5</sup> Bettinger,<sup>6</sup> and Tscherne and Schäffer<sup>9</sup> are accepted as chorionepithelioma of teratomatous origin even though histologically no teratomatous elements were found. In adults the picture is that of ectopic pregnancy with irregular vaginal bleeding and the finding of an abdominal mass.

Treatment in such cases is unsatisfactory, and the longest recorded survival after operation is eight months.<sup>13</sup> Since the diagnosis is usually made postoperatively, the proper course is controversial. The consensus is that complete operation with removal of the uterus and other ovary is indicated

if there is no x-ray or hormonal evidence of metastasis<sup>29-31</sup> Crossen<sup>32</sup> prefers surgery to radiation, which is of little value in this type of tumor

The following case of teratomatous chorion-epithelioma of the ovary is considered worthy of report because of the rare occurrence of this type

to be densely adherent to the right posterior peritoneum, and extended deep into the pelvis. The entire mass, including the right tube, was dissected free and removed without difficulty. No gross evidence of metastasis was noted. The uterus, left tube and left ovary appeared normal. The immediate postoperative course was uneventful. On the 3rd postoperative day the patient began to menstruate for the first time, and although bleeding was not excessive,

TABLE 1 *Proved Cases of Primary Chorionepithelioma of the Ovary according to Year of Publication*

AUTHOR	YEAR	AGE OF PATIENT	SYMPTOM	SURVIVAL AFTER OPERATION

of neoplasm, with a scarcity of reports in the literature, and because of the hopeless prognosis offered, irrespective of the type of treatment administered

CASE REPORT

S F, an 11-year-old Italian girl, was first seen in the accident ward of the hospital on December 12, 1946, complaining of low abdominal pain. She was observed for 24 hours and discharged, improved, with a diagnosis of mesenteric adenitis. She returned to the hospital on January 19, 1947, again complaining of low abdominal pain, which had suddenly occurred 5 hours before admission and was limited to the hypogastrium. The pain was constant, dull and not accompanied by nausea, vomiting or bowel change. There were no urinary complaints, vaginal discharge or bleeding. Neither chills nor fever had been noted, and the patient had never menstruated.

Other than the usual childhood diseases, no serious illnesses had been contracted and the family and social histories were irrelevant.

Physical examination revealed a thin, but well developed girl, who was in no acute distress. The heart was within normal limits, and no murmurs were present. The lungs were resonant throughout, with no rales or abnormal breath sounds. Palpation of the abdomen revealed an ill defined, lemon-sized mass in the right lower quadrant, which extended 5 cm. above the symphysis to the right of the midline. It was freely movable, hard and nontender. No muscle spasm or fluid wave was present. The vaginal orifice was infantile, but rectal examination disclosed a rather firm mass bulging into the rectum, it did not appear to be attached to the uterus. In view of the fact that the patient had had a similar attack 6 weeks previously it was believed that she had appendicitis, with rupture and abscess formation, although the white-cell count was only 6400, with 61 per cent neutrophils, and the sedimentation rate 35 mm in 1 hour.

The temperature was 98.6°F, the pulse 100, and the respirations 20. The blood pressure was 85/55.

On January 21 a laparotomy was performed under nitrous oxide, oxygen and ether anesthesia through a low-midline incision. The appendix was easily located and found to be normal. On further exploration, a large hemorrhagic necrotic tumor of the right ovary was clearly visualized. It proved

the hemoglobin gradually fell to 49 per cent and multiple transfusions of whole blood were given. Except for continued weakness, she was apparently in good condition. Further surgery was considered to be inadvisable until a positive pathological report of a malignant lesion could be verified, and radiation therapy was considered only as a

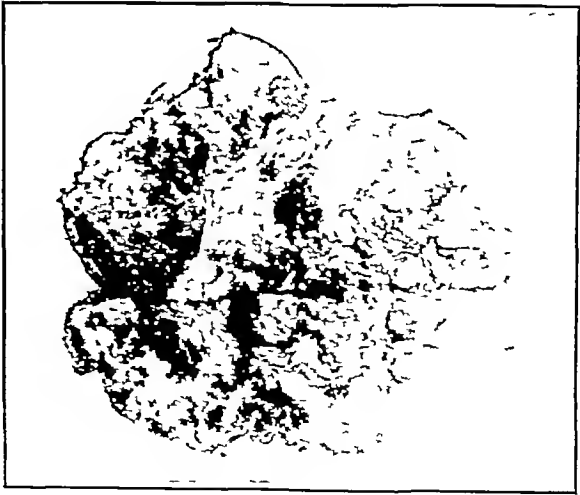

FIGURE 1 *Photograph of the Tumor of the Ovary*

last resort. A Friedman test was negative on February 1, but strongly positive on February 10 and positive with spinal fluid on February 17. No evidence of metastases was found by x-ray examination on January 29 and February 15 and 22. X-ray therapy was started on February 26, and continued through March 25. The patient received twenty-one treatments for a total of 4000 r given in four different fields. The hemoglobin continued to remain between 50 and 60 per cent,

despite repeated small transfusions until March 23, when she had improved clinically to the extent that she was afebrile and asymptomatic with a rise in hemoglobin to 75 per cent. She was discharged on the 65th hospital day. The Friedman test remained strongly positive with dilutions of urine, uninfluenced by the radiation therapy. By April 15 she was losing weight and was unable to return to the tumor clinic for follow-up examination. Her family physician stated that a nontender mass had developed in the lower abdomen and gradually enlarged, reaching to the xiphoid process before

four years, only 3 other proved cases have been found in the American literature. The diagnosis was not made preoperatively, and the gross disease was difficult to recognize. Evidence of precocious sexual development was not noted.

The prognosis is poor as illustrated in the case reported, death occurring in all cases in less than a year. Removal of the uterus and other ovary at the time of the original operation might have prolonged this patient's life, although this point is controversial even among leading gynecologists. Treatment at its best is unsatisfactory. More case reports should be forthcoming if this interesting tumor, which presents an unfavorable outcome, is to be recognized.

FIGURE 2. Photomicrograph of the Ovarian Tumor, Showing the Islands of Langhans and Syncytial Cells Imbedded in Hemorrhagic Tissue.

death. The patient expired suddenly 4 months after operation. Permission for autopsy was not granted.

Macroscopic examination was as follows (Fig. 1).

The surgical specimen consists of an ovary and tube. The ovary measures 7.5 by 7 by 7 cm. The surface is smooth and shiny with a mottled blue and red sheen except for a small shaggy area. On section, some areas are yellow and caseous, and others are dark brown and firm. Between these areas the surface is hemorrhagic. There are numerous cysts scattered throughout the ovary, the largest measuring 2 cm in diameter. They have a smooth shiny lining. The tube measures 5.5 by 0.5 cm. The serosa is smooth and glistening, the lumen patent throughout, and the mucosa normal. The mesosalpinx is normal.

Microscopical examination was as follows (Fig. 2).

The capsule consists of partially hyalinized connective tissue, which contains foci of lymphocytes. Beneath the capsule are scattered areas of normal ovarian stroma with a few follicles lined by a single layer of columnar and cuboidal epithelium. The macroscopic cysts have a definite wall of stratified squamous epithelium. The greater part of the cortex and medulla, however, is markedly hemorrhagic, with large areas of necrosis. Adjacent to the hemorrhagic areas are several masses of round to cuboidal cells varying greatly in size. They have a distinct cell outline and a clear cytoplasm with a round, dark nucleus, and represent Langhans cells. These cells are separated into small clusters by large cells, which have an indefinite cell wall. They are deeper staining and contain irregularly shaped, dark nuclei, some of the cytoplasmic masses being multinucleated. These represent syncytial cells. Mitoses are not seen.

#### SUMMARY

A case of primary teratomatous chorionepithelioma of the ovary in a young girl is reported. This appears to be the fourteenth authenticated case report, none having been reported in the past

## YAWS IN MASSACHUSETTS\*

JOHN G. DOWNING, MD †

BOSTON

**Y**AWS can occur in Massachusetts. Several physicians refused to believe this possibility and doubted the history given on several occasions by the mother of the patients in the cases reported below. The return of overseas veterans and the rapidity of transportation increase the likelihood of sporadic cases of tropical diseases. A carefully taken history, including recent change of abode, is important. The diagnosis in both these cases was promptly made by the original observers in Jamaica.

Ease of transmission, owing to abundance of the etiologic agent on the exposed skin, makes yaws a serious disease in crowded neighborhoods. It must be considered in the differential diagnosis of persistent granulomas. History, dark-field examination and serology of a patient presenting echthymatous lesions will readily establish the diagnosis, especially in children, because it is a nonvenereal disease.

## CASE REPORTS

**CASE 1** E. R., an 8-year-old Negress, was seen in the Boston City Hospital Out-Patient Department on September

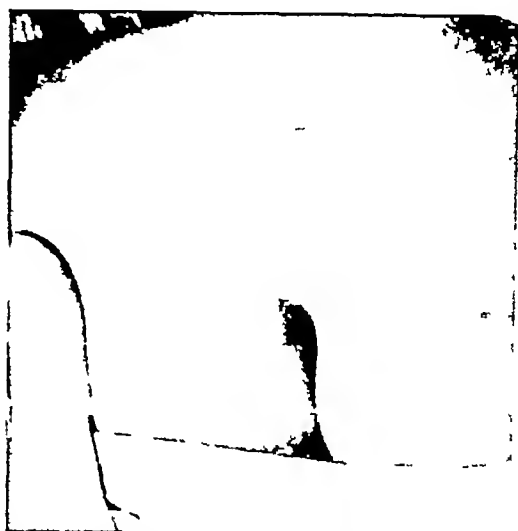

**FIGURE 1** Photograph of the Right Heel in Case 1, Showing an Inverted Saucer-like Granuloma.

Dark-field examination of the serum showed *Treponema pertenue*.

ber 24, 1947, complaining of sores on the right heel and left buttock. The history revealed that her family had lived on the island of Jamaica, British West Indies, from 1945 until August, 1947. On April, 1946, she had stepped on a tack, and a crusted area had subsequently appeared. It per-

sisted for months until the patient was seen by a district nurse, who diagnosed the lesion as yaws. The diagnosis was confirmed by laboratory studies at the hospital, and treatment consisting of a few doses of bismuth and salvarsan was given. After the first treatment, the patient suffered a generalized "measle-like" eruption, which with the initial lesion disappeared after treatment. In July a blister appeared on the right heel and became crusted. It was present

**FIGURE 2** Photograph of the Left Buttock in Case 1, Showing the Frambesiform Lesion of Yaws.

on her return to the United States in August, and assumed the appearance seen on September 15. The lesion was circular, 5 cm in diameter, elevated, crusted and indurated, with a surrounding ring of satellite vesicles (Fig 1). Dark-field examination showed *treponemas*. Further examination revealed a similar lesion on the left side of the intergluteal fold (Fig 2). The blood Hinton test was positive. The patient was given 4,000,000 units of penicillin.

**CASE 2** D. R., the 5-year-old brother of the patient in Case 1, was seen on October 10, 1947, when examination showed a sore on the left heel and left buccal mucous membrane. The history revealed that 6 months previously, while living in Jamaica, he had injured his leg, and a lump that crusted had appeared. It was diagnosed as yaws, and he received three injections of bismuth and seven injections of salvarsan. The lesion had healed when he returned to the United States in August. On October 1 the left heel had broken down, and his mouth became sore. Examination showed a small superficial ulceration on the left buccal mucous membrane and an indurated, crusted ulcer, 1.5 cm in diameter, on the left heel. Many enlarged nontender nodules were present in the post-cervical area. Dark-field examination showed many *treponemas*. The blood Hinton test was doubtful on October 10 and strongly positive on October 15. This patient was also given 4,000,000 units of penicillin.

## DISCUSSION

In the differential diagnosis of persistent granulomatous lesions in addition to reactions to drugs

\*From the Department of Dermatology, Boston City Hospital.

†Professor of Dermatology, Tufts College Medical School and Boston University School of Medicine.

including bromides, syphilis, tuberculosis and deep-seated mycotic infections, yaws must be considered. Although it is endemic in the East and West Indies and equatorial areas, sporadic cases may be seen in the United States.

The primary lesion is almost invariably extragenital, occurring most often on the lower extremities, usually at the site of recent injury. *Treponema pertenue* is the etiologic agent that invades the blood stream. The primary lesion is found, after three or four weeks' incubation. It is usually an elevated ulceration with constant crusting. The secondary lesions start as macules, becoming papules and later typical frambesiform lesions. These are elevated nodules, from 1 to 2 cm in diameter, often covered by dried serum. When this dried serum

is washed off, a round, pink, lobulated surface resembling a raspberry is seen. Such a lesion was present on the patient's heel in Case 1. Washing the surface of a crusted ulceration with soap and water is often very revealing. It may show a carcinoma, syphilis, yaws or blastomycosis, all of which have characteristic clinical pictures. Penicillin apparently successfully arrests this disease and perhaps cures it.

#### SUMMARY

The possible occurrence of yaws in Massachusetts, as well as the points to be considered in diagnosis and treatment, is briefly discussed.

Two cases that occurred in residents of Massachusetts who had lived in Jamaica are reported.

520 Commonwealth Avenue

## MEDICAL PROGRESS

### MALARIA\*

QUENTIN M. GEIMAN, PH.D.†

BOSTON

IN 1943 an article was written to review the significant concepts and facts about malaria among human beings.<sup>1</sup> In that account, a brief allusion was made to the comprehensive program placed in operation by the armed forces to control malaria. Nothing could be said at that time about the extensive mobilization of clinicians, chemists, parasitologists and entomologists and the training of skilled personnel to attack unsolved malarial problems, which were of extreme strategic importance to the Allies.

Sufficient time has elapsed since the close of World War II to evaluate the foremost advances made in the knowledge of malaria in human patients during and since the conflict. The majority of advances arose out of laboratory and field solutions to problems of diagnosis, prophylaxis, treatment and control that confronted the armed forces fighting in tropical areas. Fortunately, many of the advances, particularly in chemotherapy, were made and applied in time to aid in tipping the balance in favor of the Allies during operations in malarious areas. In the words of Russell<sup>2</sup> "Military experience taught once more that the prevention of malaria is neither automatic nor simple but is compounded of law and persuasion, organiza-

tion and training, supplies and technical applications."

The necessity of war forced the expenditure of large sums of money, which speeded the production, organization and application of newer insecticides to the drastic control of malaria in heavy malarious areas. The results have been so satisfactory that malarialogists are predicting the complete eradication of malaria from this<sup>3</sup> and other countries<sup>4</sup> if the new weapons for control are used wisely. A discussion of the development of insecticides and methods for their use against malarial vectors and other arthropods that transmit tropical diseases is not within the scope of this paper. It is sufficient to say that the continued intelligent and skilled uses of the newer methods of mosquito control and the proper use of new antimalarial drugs will go far in reducing the menace of malaria to that of a minor tropical disease. Unfortunately, the existence of lethal insecticides and effective antimalarial drugs does not guarantee their proper use in hyperendemic malarious areas where the problem equals that which existed prior to World War II.

The purpose of this article is not to give a comprehensive account of progress in malariology or to argue in favor of new methods for the treatment of malaria and the control of anopheline mosquitoes. The contributions considered add to the basic knowledge of the parasites, to clinical knowledge of the course and sequelae of the disease so that a prompt diagnosis can be made and to methods of treatment.

\*From the Department of Comparative Pathology and Tropical Medicine, Harvard Medical School.

The material reviewed in this paper was compiled in connection with a malaria-research project supported by a grant in aid to Harvard Medical School from the Division of Research Grants and Fellowships of the National Institute of Health, United States Public Health Service.

†Assistant professor of tropical diseases, Harvard Medical School.

## THE PARASITES

Pertinent information about the mechanism of disease production by malarial parasites was reviewed previously.<sup>1</sup> The precise biochemical basis for the interpretations is just beginning to unfold. Growth and multiplication of mammalian plasmodia in vitro have been obtained,<sup>2, 6</sup> and the methods developed for the studies have provided tools to determine the physical and chemical requirements for growth and nutrition of the parasites.<sup>7, 8</sup> The medium developed for these studies is the result of attempts to devise a synthetic plasma, containing inorganic salts, sources of calories such as glucose, glycerol and sodium acetate, amino acids for protein synthesis, vitamins, para-aminobenzoic acid, purines and pyrimidines. Of these substances, glucose, para-aminobenzoic acid<sup>8</sup> and methionine<sup>9</sup> have been established as essential nutrients for *Plasmodium knowlesi*, and the other ingredients appear to be accessory growth-promoting compounds. These studies also showed that the malarial organism cannot survive on the available hemoglobin and cytoplasm of the red cell. The plasma must supply other nutrients for diffusion through the cell membrane if the parasite is to grow and metabolize normally and produce progeny or merozoites for reinvasion of other erythrocytes. Thus, there are plasma or host factors that control levels of parasitemia and perhaps pathogenesis of malarial parasites.<sup>10</sup>

In 1943 and 1947 Trager<sup>11, 12</sup> reported on the effect of biotin and a biotin-like substance upon susceptibility to avian malaria. This work was confirmed and extended by Seeler and his collaborators<sup>13-16</sup> to experiments with riboflavin, thiamin, folic acid and protein deficiencies. Rigdon<sup>17</sup> failed to detect any effect of vitamin A deficiency on *P. lophurae* in ducks.

The cultural studies with mammalian parasites in vitro have pointed the way to a further extension of studies in vivo. Monkeys (*Macaca mulatta*) deficient in ascorbic acid<sup>18</sup> will control spontaneously an infection with *P. knowlesi*. The absence of methionine from the diet of monkeys and monkeys on fast will also control this highly pathogenic organism.<sup>19</sup> This work is of fundamental importance and the results of more experiments will be followed with interest.

Direct biochemical studies of suspensions of avian and mammalian plasmodia show that the parasitized erythrocytes consume twenty-five to seventy-five times more glucose than the normal red cells.<sup>20, 21</sup> *P. knowlesi* and *P. gallinaceum* contain proteolytic enzymes, which are capable of splitting, degrading<sup>17</sup> and synthesizing protein.<sup>21, 22</sup> The finding that *P. gallinaceum* produces amino nitrogen and ammonia as by-products of protein and glucose under certain conditions<sup>22</sup> might lead

the way to studies that will prove or disprove the production of "toxins" by malarial parasites.

The sequence of events in avian malaria between the bite of an infected mosquito and the blood stages of the parasites has been worked out in detail by Huff and Coulston.<sup>23, 24</sup> These studies are outstanding contributions to malariology. Infective mosquito stages of the malarial parasite, *P. gallinaceum*, were inoculated into young chicks. The chicks were killed at given time intervals and examined histologically. In this way the precise development of the sporozoites (infective stages) through stages called cryptozoites and metacryptozoites within fibroblasts and other lymphoid cells was discovered. The stages resulting from this tissue development emerged later into the blood stream to reinvade the erythrocytes. Although similar stages have not been found in any of the malarias occurring in human beings, they have been found<sup>25, 26</sup> in the parenchymal cells of the liver in monkey infections with *P. cynomolgi* and verified by Hawking.<sup>27\*</sup>

It is believed that such tissue stages exist at least in benign tertian malaria (*P. vivax*) of man and that they are the basis for the serious relapsing nature of this type of malaria. The exact reasons for the relapsing nature of *P. vivax* have not been determined satisfactorily. The explanations that are accepted at present are based by inference on experiments in vivo conducted before the war and later during the war by Fairley and his collaborators<sup>28</sup> in Australia and by the discovery of the so-called "tissue stages" in avian malaria mentioned above. The infective stages, or sporozoites, injected by female anopheline mosquitoes, do not enter the circulating erythrocytes immediately. Patients inoculated experimentally by infected mosquitoes did not have circulating blood parasites from about thirty-six hours to times ranging from two hundred and six to two hundred and fifty-four hours after the infective bite. This was proved by transfusions of large quantities of blood (200 to 500 cc) from infected patients to normal persons. Parasites could be found on an average of twelve days (range, ten to seventeen days) after exposure. These results indicated that tissue stages of *P. vivax* must exist and that the time required for their appearance differs with species and perhaps strains of parasites.

Similar experiments with *P. falciparum*<sup>28</sup> gave negative blood tests up to one hundred and forty-four to one hundred and sixty hours after the infective bite, and parasites could be demonstrated seven to twelve days after the bite.

It is also believed that the inability to obtain radical cures of relapsing tertian malaria with anti-malarial drugs is due to the failure of these drugs to penetrate and exert a lethal action on tissue

\*Since this paper was received for publication the tissue stages of *P. vivax* have been discovered and described by Professor Shortt at the Fourth International Congresses on Tropical Medicine and Malaria.

stages of the plasmodia. The ease by which it is possible to cure benign tertian malaria in paretics who receive their infection by the passage of infected blood gives credence to the theory. These patients receiving malaria induced by blood passage have no tissue stages, and therefore radical cures can be effected with antimalarial drugs. It remains to be determined experimentally whether or not the ability to obtain radical cures of naturally acquired malignant tertian (*P. falciparum*) infections with drugs (a point discussed below) means that the hypothetical tissue stages do not exist or that they are more susceptible to drugs if they do exist.

### DIAGNOSIS

The laboratory detection of malarial parasites in blood films still remains the most reliable method for the diagnosis of malaria. Advances in staining technic of thin and thick films have been directed toward obtaining a more speedy and satisfactory stain.

The basic technics, discussed previously,<sup>1</sup> continue to be used and relied upon. However the requirement of ten to forty-five minutes to obtain stains with various modified Giemsa technics was supplanted during the war by the more rapid Field stain.<sup>29</sup> More recently, another procedure, the J S B stain, appears promising.<sup>29, 30</sup> The handicap to these methods lies in the fact that the stains are not available commercially. The stains for the solutions must be compounded in the laboratory by a combination of standardized stains, methylene blue and eosin. The Field stain, furthermore, is not so permanent as Giemsa's stain. The J S B stain appears to be permanent, but insufficient time has elapsed since its development to be certain about its permanency.

An interesting colorimetric test for malaria has been devised that deserves further investigation and trials. Since serologic and other known tests for malaria fail too frequently during intervals between relapses and in latent malaria, Carlson, Mueller and Bissell<sup>31</sup> sought a new test. In recognition of the changed nature of the host's blood plasma during malaria and the known combining qualities of colloidal dyes with proteins, a test using dyes as indicators to detect the changes in plasma was devised. The test developed by these authors makes use of Congo red, quinine hydrochloride and the serum to be tested. The test gave positive results when tested against *P. knowlesi*, *P. allinaceum* and *P. vivax* infections.

### IMMUNITY

During World War II, the seriousness of white people contracting malaria when going into malarious areas was greatly increased by the necessity of operations in the tropics. Immunity can be acquired to the disease by natives but only by constant infection or reinfection with local strains of

parasites throughout life. The mechanism of acquiring immunity involving both antibody production and cellular defenses was reviewed previously, and the poor antigenicity of the parasites and the low protection of immune serum were discussed.<sup>1</sup> Few contributions have been made to alter the theories and interpretations expressed at that time. The advances, by necessity, have been concerned with practical serologic tests that could be used to detect quiescent malarial infections and characterize the strains of parasites encountered in diverse areas.

Relapsing tertian malaria contracted in the Mediterranean and Pacific theaters of World War II became a diagnostic problem of great importance. Since parasites cannot always be detected by laboratory methods during intervals between relapses, serologic tests, particularly the complement-fixation test, offered a possible solution to the difficulties.

In 1938 Coggeshall and Eaton<sup>32</sup> demonstrated the complement-fixation reaction for malaria. They showed that the reaction was group specific and that the simian and avian species of parasites could be used as antigens. The test subsequently was applied in the field to malaria in human beings by Dulaney and Stratman-Thomas<sup>33</sup> and Kligler and Yoeli.<sup>34</sup> This work was limited in extent, and during the war it became worth while to determine the value of the test in detecting *P. vivax* infections.

Extensive laboratory experimentation and field trials with the reaction produced a refined test that could be used with greater precision<sup>35, 36-37</sup> than originally. This new procedure failed to give the desired results in detecting the existence of relapsing malaria. The conclusion was reached that the test was still a supplementary rather than a dependable single diagnostic procedure. The work of Mayer and Heidelberger<sup>38</sup> showed that a single test with serum from a patient with suspected malaria was of value only if positive, but if negative, malaria could not be excluded. Furthermore, these authors make the following statement:

The reaction diminished 1-6 weeks after relapses only to increase again shortly before or during or immediately after a subsequent relapse. Similar fluctuations may occur, however, without a clinical relapse rendering predictions hazardous.

These fluctuations occurred with a crude vivax antigen, or with normal red-cell stromata antigen.<sup>39</sup> The "soluble," more purified vivax antigen that Mayer and Heidelberger developed gave no such fluctuations, and it aided these workers in discovering for the first time a species specificity with complement-fixation methods. By the use of this "soluble" vivax antigen it was discovered that a positive complement-fixation test did not indicate the existence of protective immunity, since patients were observed who relapsed despite the detection of antibody in serum drawn shortly

before an attack. The results of Dulaney and Watson,<sup>36</sup> who used a "crude" antigen further illustrate this point.

Heidelberger et al.<sup>40, 41</sup> also attempted to protect patients with relapsing vivax malaria by treatment with a homologous vaccine. These experiments were well controlled, and the relapse rate in the vaccinated groups was the same as that in the controlled groups. A further attempt was made by Heidelberger and his co-workers<sup>42, 43</sup> to vaccinate patients against subsequent blood-borne infections and mosquito-borne infections with *P. vivax*. The patients, when infected with malaria three weeks after the last injection of vaccine, came down as usual with malaria, thus, no protection was obtained by vaccination. These very thorough studies verify previous results with animal malarial infections. For reasons unknown, the asexual stages of parasites appear to be very poor antigens. Freund et al.<sup>44-46</sup> were able to protect monkeys and ducks against malaria by using a vaccine containing asexual parasites, an adjuvant, emulsifying agent, and killed tubercle bacilli, but this method of vaccination has not been tried against malaria in human beings. Freund<sup>47</sup> reviews the theory and facts about this type of active immunization in a recent paper.

The development of false-positive tests for syphilis in patients with naturally acquired or artificially induced malaria has been the subject of extensive study. The need for clarifying the basic phenomena that cause positive syphilitic tests in patients having only malaria and for publicizing the occurrence among physicians became necessary to avoid placing under treatment for syphilis persons who do not have the disease. One book<sup>48</sup> and two review papers<sup>49, 50</sup> present the subject thoroughly. The results of a detailed study by Rein and Kent<sup>51</sup> of 7493 serums obtained at suitable intervals from 90 nonsyphilitic volunteers with naturally induced malaria are important. Some of the patients were studied as long as eighteen months. Each serum was subjected to a battery of 7 serodiagnostic tests for syphilis, and 44,958 tests were performed. Of the 90 infected subjects 57 (63.3 per cent) developed false-positive reactions with one or more tests during the course of the disease. The Hinton flocculation and micro-flocculation test employing a cardiolipin antigen yielded results of high specificity and the highest percentage of false-positive tests was obtained with the Kahn standard test. The results showed that false-positive tests for syphilis were highest in early primary malaria, lower in delayed primary attacks and lowest in relapses. Thus, any patient with a recent history of malaria or with a history of living in an endemic malarious area and a positive blood test for syphilis should have the existence of malarial infection ruled out before syphilitic treatment is instituted.

## PHYSIOLOGIC PATHOLOGY

During World War II, malaria was an acute problem to the armed forces and personnel stationed in endemic areas. The problem involved not only the diagnosis and treatment of the clinical disease but also returning a man to full-time or limited duty or back to the United States from overseas. Later, after discharge from the services, the amount of disability to which a previous malarial patient was entitled had to be determined. Thus, criteria of radical cure and an investigation of physical and functional effects of the disease on the host had to be established. Too often misapprehension on the part of the patient was aided and abetted by the unfamiliarity of the physicians with the course and results of the infection.

As a result of experimental and field trials, quinacrine (synonyms, atabrine and mepacrine) was found to be a true causal prophylactic and a radical cure for infection with the malignant tertian parasite *P. falciparum*. The majority of the problems resulting from malarial infection had to do, then, with relapsing tertian malaria. Several investigations were conducted by the Army and Navy to discover the organic and the psychologic causes for morbidity produced by *P. vivax*. These investigations were very thorough, they were conducted independently of each other, and the results add greatly to knowledge of the course of this infection and the sequelae from the disease. These results are of distinct value in determining procedures concerned with the disability granted by the Veteran's Administration to persons who previously had an infection with malaria.

In the first study of Tumulty et al.,<sup>52</sup> 50 soldiers who had suffered recurrent attacks of benign tertian malaria were selected. These soldiers were subjected to a long period of functional, metabolic and psychiatric tests. The evaluation of each soldier and his physical and mental condition was extended over a period of seven days. The procedures are not mentioned in detail, but they included a complete history and physical examination, basal metabolic rate, liver-function test, neurologic test, clinical pathologic test, hematologic test, stool examinations for ova and parasites and serologic test for syphilis.

It is impossible to give in detail the methods of testing used in this study and the very careful evaluation and interpretation of the results. The 50 patients revealed no evidence of damage or dysfunction of the organic systems measurable by the technics employed. The authors believed that the absence of such organic changes was the result of the fact that these patients were treated adequately and early in their attack. However, weight loss, weakness and debility in varying degrees were present in all but a very few of the pa-

tients The chronic symptomatology found in these soldiers was believed to be caused primarily by malaria However, the way the patient adjusted himself to the disease and the environmental factors present at the time of illness were believed to contribute greatly to the development of the symptoms

A second series of studies by Bianco et al<sup>53</sup> differs from those of Tumulty in the fact that they extended over a period of twenty-six months During this time 1500 attacks of malaria were observed, and the persons studied were tested in ways that coincided in some cases with the tests used by Tumulty and his associates but differed in other respects

All the men examined in this study were either Marine or Navy personnel One third of the men had recently returned from overseas duty, and two thirds had been back in this country two to eighteen months without having had intervening quinacrine therapy It is important to note that these authors refused to admit a patient to their study without first having found definite malarial parasites to establish the diagnosis of malaria It was found that the information given by the patient and the available history were unreliable in many cases, and thus competent technicians were used to arrive at the diagnosis of malaria in the presence of fever and with or without an enlarged spleen The technicians never failed to find parasites in the peripheral blood within seventy-two hours when thick smears were examined at eight-hour intervals It should be noted further that parasitemia was commonly of low density, revealing itself, however, during the first few days of clinical malaria The blood-smear technic was of no value if the patient had taken antimalarial drugs several days previously or if a clinician had prescribed sulfonamides to the patient, thinking that fever was due to another infectious agent

Some of the findings that these authors report include the absence of the chronically enlarged spleen, although the spleen in a number of cases was palpable during an attack of acute malaria Leukopenia was fairly common The erythrocyte sedimentation rate was increased in 68.9 per cent of the cases during the acute attack, and in 16.3 per cent during the remission stage of the disease The icteric index was also increased during an acute attack Some of the complement-fixation tests failed to show any relation between parasitemia and the development of subsequent relapse The results with the serologic tests for syphilis were as follows: a variety of tests or methods of testing were used, and the authors found that in a more or less random sample of serum from patients taken during clinical malaria and between attacks, about 90 per cent of the results were negative Positive reactions increased during the second and third weeks after the onset of

clinical malaria, but the serum became negative in most cases within four weeks and in all cases within ten weeks after onset The importance of these tests is included in the statement that 20 to 30 per cent of the cases gave positive reactions by one or more of the tests used two to three weeks after the onset of clinical malaria Positive tests, however, were almost never found later than four to six weeks after onset

The attempt on the part of Bianco and his collaborators to pin down the exact mechanism underlying malaria relapses is worth commenting upon Their purpose, in part, was to allay the fears of many medical and lay personnel that "South Pacific" malaria meant a long if not permanent disability Studies on the relapses and associated symptoms, length of time between relapses, precipitating causes and reactions to treatment led to the following conclusions "With the passage of time away from highly endemic areas, the frequency and severity of relapses shows an unmistakable trend toward the eradication of the malaria within 3 years by development of immunity in the host" Furthermore, they state that "many of the alleged postmalarial sequelae bear no relation to malaria *per se*, but are rather directly related to the personality of the individual"

(To be concluded)

BENJAMIN CASTLEMAN, M.D., *Associate Editor*

EDITH E. PARRIS, *Assistant Editor*

### CASE 34271

#### PRESENTATION OF CASE

A fifty-eight-year-old unmarried woman, a floral designer, entered the hospital complaining of abnormal vaginal bleeding.

The patient underwent a normal menopause ten years before entry. Her periods prior to that time had always been regular. Since the menopause she had had no vaginal bleeding until six weeks before entry. At that time she noted enough bloody staining to require the wearing of a pad. This bleeding recurred every three or four days until three weeks before entry, when the bleeding occurred almost every day. It was never profuse, was not accompanied by pain and was otherwise asymptomatic.

She had lost no weight. Two weeks before entry a vaginal smear was reported negative.

The family history and past history and a review of the systems were noncontributory.

Physical examination showed a well developed, well hydrated, obese woman. The heart was slightly enlarged, the border of cardiac dullness extending to the left. The blood pressure was 150 systolic, 95 diastolic. In the abdomen was a movable, nontender mass arising from the pelvis and extending to the level of the umbilicus. Vaginal examination revealed the presence of old blood. The cervix itself was clear. Rectovaginal examination disclosed a large mass filling the pelvis, rising nearly to the navel. It was more prominent on the left and could be moved somewhat. Movement of the mass produced motion of the cervix, and the two seemed to be connected.

The urine was normal, and the hemoglobin was 13.6 gm.

On the day after entry an operation was performed.

#### DIFFERENTIAL DIAGNOSIS

DR. WARD I. GREGG. In this fifty-eight-year-old unmarried woman, whose periods were always regular and who had lost no weight, bleeding had been active for three weeks but present off and on for six weeks.

The causes of postmenopausal bleeding ten years after the menopause I will name and discuss as we go along. The most common cause occurring in 50 per cent of postmenopausal bleeders is adenocarcinoma of the fundal portion of the uterus. Today the next most frequently observed cause—but perhaps in this case not quite so important—is the use or misuse of various estrogens for menopausal symptoms. Proliferation or even hyperplastic endometrium can be produced by continued ingestion of estrin at any age. In this case, however, ten years with no mention of menopausal symptoms is rather late for symptoms to develop. We can forget about that.

To proceed to the findings on physical examination, the patient had a large pelvic mass, which extended up above the pelvic brim almost to the umbilicus and was consistently felt as one mass. We have all examined women and found that one mass may actually consist of a number of adherent masses over the uterus. For the purpose of this discussion we should consider this one mass connected with the cervix and assume that it was the uterus. It was a large uterus, and the next possible diagnosis is therefore a degenerated fibroid. This is apparently rare unless it was a submucous fibroid in which ulceration had occurred. Another possibility that we see from time to time is a polyp, either endocervical or endometrial. Polyps sometimes ulcerate, bleed and produce symptoms similar to those in the case under discussion. Ten years after the menopause is a short period for atrophic vaginitis. Also, the bleeding of atrophic vaginitis rarely becomes constant like that which occurred during the first three weeks of this woman's illness. Carcinoma of the ovary, with bleeding as the primary symptom, is rare unless it has invaded the endometrium. The same statement is true of carcinoma of the Fallopian tube, in which bleeding occurs very rarely until the carcinoma has penetrated the endometrium by way of the tube. It is a possibility but not likely. A year ago a patient was presented to me with an almost identical history, and she had a carcinoma of the Fallopian tube.

I think probably the point of greatest significance here is the fact that two weeks before entry a vaginal smear was reported negative. One vaginal smear, if positive, may mean that the patient has an endometrial carcinoma. However, in the experience of the Vincent Laboratory 23 per cent of proved adenocarcinomas of the endometrium have had negative smears. Scheffey et al.<sup>1</sup> in Philadelphia, have found 40 to 50 per cent of proved adenocarcinomas with negative smears. A negative smear does not rule out completely the possibility of adenocarcinoma. The frequency with which fibroids appear along with carcinoma of the fundus runs in the neighborhood of 33 per cent. The rather scanty bleeding in this particular case may

point toward a small, early lesion. But an advanced carcinoma may break down late. The other thing of importance is that this patient was an unmarried woman, and it has been shown in various series that adenocarcinoma is more likely to develop in nulliparous women who have been exposed to long, uninterrupted estrogen levels. The same group of people usually have dysfunctional bleeding with anovulatory cycles at the climacteric. Randall<sup>2</sup> pointed out in his series that about 45 per cent of postmenopausal adenocarcinomas occurred in women who had dysfunctional bleeding at the time of the climacteric, although the carcinoma was not evident until years afterward. I therefore have a strong feeling that this patient had a uterine fibroid and adenocarcinoma of the endometrium.

#### CLINICAL DIAGNOSIS

Ovarian cyst?  
Degenerating fibroid uterus?

#### DR GREGG'S DIAGNOSIS

Adenocarcinoma of the uterus, with uterine fibroid

#### ANATOMICAL DIAGNOSES

*Adenoacanthoma of fundus of uterus*  
Follicle cyst of ovary  
Uterine leiomyomas

#### PATHOLOGICAL DISCUSSION

DR W. PHILIP GIDDINGS: Dr. Arthur W. Allen thought that the mass, of which, as I recall it, the patient was not aware, represented ovarian disease of some type. She was operated on with a diagnosis of ovarian cyst. Prior to laparotomy a curettage was performed, and grossly carcinomatous material was obtained. At laparotomy a slightly enlarged uterus and a large cyst of the ovary, arising on the left side, were removed.

DR BENJAMIN CASTLEMAN: Although the large mass that was felt was an ovarian cyst, there was, in addition, a uterine fibroid 2 cm in diameter. I do not believe that it had much to do with the adenocarcinoma that was located in the fundus. In a few areas the cancer showed some squamous cell metaplasia, making it an adenoacanthoma. The ovarian cyst was smooth, both inside and out, and perfectly benign.

DR HOWARD ULFELDER: It would be interesting to know if the vaginal smear showed estrogen effect. In a woman of this age estrogen effect in a vaginal smear is found much more frequently in women with adenocarcinoma of the fundus.

DR GREGG: Along with that there is another point that comes up. An estrogen effect in a vaginal smear can occur with granulosa-cell tumor of the ovary. A granulosa-cell carcinoma of the ovary

and an adenocarcinoma of the endometrium are frequently found together and could be caused by the constant estrogen stimulation. I do not believe that the amount of bleeding or the duration indicate such an effect in the case under discussion.

DR CASTLEMAN: The endometrium away from the carcinoma was of the atrophic senile cystic type, which some people believe is a precursor of adenocarcinoma.

#### CASE 34272

##### PRESENTATION OF CASE

A twenty-seven-year-old housewife entered the hospital complaining of an itching rash.

Two years before entry, about three months after the birth of her first and only child, the patient developed itching lesions on the left ankle. These gradually spread until a pruritic dermatitis involved the legs, arms and trunk, and even spread to the face and scalp. A slight remission of the dermatitis was noted on two occasions, lasting for several weeks, but each time the dermatitis returned as before. She had been seen by many physicians and had had a variety of treatments, including allergy tests, antihistamines, local applications and x-ray therapy to localized skin areas, all with little or no effect. Four months prior to admission the patient was given penicillin tablets by mouth for the appearance of some enlarged cervical lymph nodes. One week after the penicillin was discontinued she developed a generalized urticaria, and she had repeated attacks of urticaria up until the time of admission.

Physical examination revealed a moderately well developed and well nourished young woman, who was nervous and emotionally upset because of fatigue, itching and worry. Several small firm non-tender lymph nodes were palpable along the anterior border of the sternocleidomastoid muscle and above the clavicle, measuring up to 2 cm in diameter. The skin findings were those of an urticaria with multiple excoriations on the flexor surfaces of the arms and over the scapulas, lower back and buttocks. Similar but less marked lesions were present on all other parts of the body. The rest of the examination was negative.

The temperature, pulse and respirations were normal.

Examination of the blood showed a hemoglobin of 13.2 gm and a white-cell count of 7700, with 49 per cent neutrophils, 24 per cent lymphocytes, 5 per cent monocytes, 19 per cent eosinophils and 2 per cent basophils. A blood smear showed only a slight increase in the number of platelets. The urine

was normal. A stool was guaiac negative, and no parasites or ova were found. The total serum protein was 6.90 gm per 100 cc, with 4.83 gm of albumin and 2.07 gm of globulin. The nonprotein nitrogen was 25 mg, the blood cholesterol 125 mg, the serum calcium 9.9 mg, and the phosphorus 5.4 mg per 100 cc. The alkaline phosphatase was 1.9 units per 100 cc.

A basal metabolic rate was +20 per cent. A chest film showed a rounded mass of increased density measuring approximately 6 by 7 by 9 cm in size, occupying the upper anterior mediastinum. The trachea was deviated to the left and somewhat posteriorly. The mass was smooth in outline. It did not appear to have caused any embarrassment to the aeration of the lungs. The lung fields were clear, the heart was normal in contour, the diaphragm was normal in position, and the chest cage was not remarkable. Tuberculin skin tests in dilutions of 1:10,000, 1:1,000 and 1:100 were negative. A repeat basal metabolic rate was +17 per cent. A cervical lymph node was biopsied and showed chronic inflammation. X-ray studies of the bones of the hands and feet showed no osteoporosis or osteolytic lesions. During the first two weeks in the hospital the dermatitis subsided until only a few lesions persisted on the forearms. During this period the temperature, pulse and respirations had always been normal.

On the seventeenth hospital day an operation was performed.

#### DIFFERENTIAL DIAGNOSIS

DR LOWREY F. DAVENPORT: The only complaint in this case was the persistent itching for a period of two years, with few or no constitutional symptoms. The objective findings are the changes in the differential count, the eosinophil count going as high as 19 per cent, the enlarged lymph nodes and the mass in the chest. In trying to arrive at a diagnosis it might be well at this point to review the x-ray films.

DR JAMES J. McCORT: These films were taken at the time of admission—a posteroanterior chest film, a grid film and a film of the hands. The large mass is present in the anterosuperior mediastinum, extending mostly to the right, but one can see a portion of it on the left. On the lateral film it is seen to be anterior to the trachea and has displaced this structure slightly posteriorly and to the left. There are no enlarged lymph nodes in the perihilar region. Both lungs are clear. The heart and vessels are normal. The mass is quite smooth and shows no calcification.

DR DAVENPORT: We have to decide immediately whether or not the symptom of pruritus over two years was a manifestation of a general systemic disease, or whether it was an incidental complaint and entirely unrelated to the mass in the chest. I

gather from the history that during this two-year period the patient had no symptoms referable to the chest, and her chief complaint was from the itching lesion in the skin. The abstract speaks of pruritic lesions. Pruritus, as I understand it, is a symptom — itching of the skin — without any visible change in the skin itself. It would make some difference whether there actually was a skin lesion present, or whether it was pruritus with secondary changes due to scratching.

DR JACOB H SWARTZ: When I first saw this patient she complained of generalized itching. The predominating lesions were not urticarial as stated in the record but rather excoriations, lichenification and pigmentation, with few urticarial wheals. Most of the cutaneous manifestations were secondary to scratching, although some of the lesions may have been primary and produced itching in this particular case.

DR DAVENPORT: We have to consider for the purposes of discussion the possibility that the itching was not connected with the general picture. I do not need to discuss some of the remote possibilities in the differential diagnosis. If, however, these skin lesions and the primary complaint of itching had nothing to do with the general picture as found, we must consider what could cause a symptomless mass in the anterior mediastinum. We can only go on a percentage basis in the differential diagnosis of such a mass. We have found in the past in young people that in the anterior mediastinum teratoma and dermoid cyst were more common, and neurofibromas were much more common in the posterior portion of the chest. If we assume that the fundamental difficulty was a skin lesion, we should consider such primary skin disturbances as mycosis fungoides, in which, in an occasional case, general changes throughout the body are described. It can affect various internal organs but would not explain satisfactorily this entire picture with a mass such as that seen in the x-ray film, the blood findings, the pruritus and the skin lesions.

For the purpose of differential diagnosis I believe we need discuss only two conditions. Hodgkin's disease and sarcoidosis. Hodgkin's disease is a disease of young age groups. It can cause masses of varying sizes in any of the lymph structures. It quite commonly affects the cervical lymph nodes. It can cause marked enlargement of the nodes in the mediastinum and of the hilar nodes. It can be accompanied by pruritus. As I understand it, the itching that accompanies Hodgkin's disease is in a true sense pruritus, and rarely are definite lesions in the skin associated with this condition. Hodgkin's disease, as I have said, is more common in younger age groups, and this woman was in the third decade. However, on a percentage basis, it affects males more than females. The fact that she was a woman is of no real diagnostic significance. Although a

patient with Hodgkin's disease may have a perfectly normal blood picture, quite commonly there is a slight increase in the leukocytes, and in many cases there is an eosinophilia. The pruritus in Hodgkin's disease may be a premonitory symptom and has been described as going on for months or even years before the development of signs of disease elsewhere. Hodgkin's disease, therefore, could explain everything that has been found in this patient.

Another condition that we see more and more frequently that can produce these changes is sarcoid disease. Sarcoidosis can attack at any age but is more common in young people. It is occasionally a disease with pruritic manifestations. It can and frequently does occur without any symptoms at all. Skin lesions do occur in sarcoid and they are described as elevated, dusky, indurated lesions that, I assume, are at times quite easily confused with urticaria. Itching of such lesions has been described as a distressing and continued symptom throughout the early course of the disease. Sarcoid involvement of the lymph nodes is quite common, and it can involve any organ of the body. Involvement of the hilar nodes is not uncommon. Most cases of sarcoid show a more diffuse involvement of the hilar structures than was present in the case under discussion. The involvement is usually symmetrical in distribution, and the process is apt to spread into the lung itself through a peribronchial pattern. Occasionally, it produces lasting fibrosis with permanent changes in the lung, but many cases have cleared up completely without any visible changes remaining in the x-ray films of the chest.

This scrapbasket of sarcoid is puzzling, and differential diagnosis is difficult. In the absence of histologic evidence we have to reason from negative data. Here is a patient who for two years had a generalized disease, and yet when she came to the hospital the only real complaint was itching. I know of no other situation that could cause such diffuse changes throughout the entire body and cause so few constitutional symptoms as sarcoid. Also, although I do not believe the decision is difficult in this case, we often must distinguish between tuberculosis and sarcoid. We frequently rely on the observation that the tuberculin test in probably 90 per cent of cases of sarcoid is negative. It is recognized, however, that perhaps 10 per cent of cases of proved sarcoid have a positive tuberculin test.

In trying to evaluate the significance of a positive or negative tuberculin test in a twenty-seven-year-old housewife, it would be of some interest to know whether the patient was born with a family background of tuberculosis or where she had lived. A negative tuberculin test through all its dilutions in a twenty-seven-year-old city dweller would be of definite diagnostic significance.

**A PHYSICIAN** The patient was born and brought up in New York City.

**DR DAVENPORT** Unfortunately, the tuberculin test is becoming less and less of a diagnostic aid because the incidence of tuberculosis throughout the country is dropping. In the Midwest there are several counties where no children in the schools show a positive tuberculin test. Here in Massachusetts the figures vary from 40 to 45 per cent in urban high schools to 15 per cent in suburbs such as Newton. This finding of a negative tuberculin test in a woman of twenty-seven, born and brought up in New York City, may be of definite diagnostic importance. We have, in sarcoidosis, a granulomatous disease that can cause skin lesions, severe and continued pruritus, enlargement of the lymph nodes and bizarre changes in the chest. It is a disease that is frequently accompanied by mild leukopenia with occasionally a definite eosinophilia such as that reported in this case.

I believe that the final diagnosis comes down to two granulomatous diseases, Hodgkin's disease and sarcoid. I cannot believe that this person had extensive Hodgkin's disease involving so much of the body with so few constitutional symptoms. A negative biopsy in sarcoid would be less surprising than a negative biopsy in a case of Hodgkin's disease. I should then make as my diagnosis Boeck's sarcoid disease, involving the skin, with a rather unusual involvement of the mediastinal lymph nodes.

**DR DONALD S KING** I saw this patient in consultation. I got off on the wrong track and was inclined to say that the skin lesions and enlarged lymph nodes were a separate condition from the asymmetrical chest lesion. Not having seen an itching sarcoid case, somehow sarcoid did not make much impression on my mind and I tried to bring in a benign tumor of the chest in this locality as an entirely separate condition from the skin and lymph nodes. I was influenced a great deal by the negative biopsy of the nodes. My preoperative guess was bronchiogenic cyst and then dermoid or teratoma.

**DR SWARTZ** I thought this case served as a good example to emphasize the close relation between dermatology and internal medicine. When the patient was first seen a provisional diagnosis of lymphoma was made because of a nonspecific eruption with severe pruritus accompanied by enlarged and hard lymph nodes in the supraclavicular areas, axillas and groins. This woman had the type of eruption seen in Hodgkin's disease: urticarial, morbilliform, scarlatiniform and zosteriform. Goldman,\* in 1940, reported 212 proved cases of Hodgkin's disease with cutaneous manifestations in 38 per cent. The predominant manifestations were urticaria, pigmentation and excoriations with severe itching. This patient had

these symptoms in addition to the presence of adenopathy. The chest film further confirmed the possibility of lymphoma, although the other diagnoses mentioned by Drs Davenport and King could not be ruled out without surgery.

In the presence of a nonspecific eruption I was taught to consider the following possibilities: drug eruption, blood dyscrasia, the lymphoma group, subclinical jaundice or some other systemic disease. The psychogenic factor should be considered only when the above-mentioned conditions had been ruled out. This is well exemplified in this case. This patient was treated for two years for pruritus of psychogenic origin. We recently had a case of generalized pruritus that showed only excoriations and icteric discoloration of the scleras. The diagnosis to date is carcinoma of the head of the pancreas. Systemic disease as a cause of pruritus without specific lesions should always be considered.

Sarcoid lesions of the skin look much different from those that this patient presented and are usually nonpruritic. They are infiltrated. Excoriations are absent as a rule. Dr Davenport did not have the benefit of seeing the lesions that this patient presented. I am certain that he would have excluded sarcoid if he had had the opportunity to examine the patient's skin.

**DR BERNARD M JACOBSON** On a medical consultation I considered all the possibilities mentioned so far. I also got off on the wrong track because of the two-year duration of symptoms of itching in a healthy-looking girl.

#### CLINICAL DIAGNOSIS

Bronchiogenic cyst?  
Lymphoma?

#### DR DAVENPORT'S DIAGNOSIS

Sarcoidosis

#### ANATOMICAL DIAGNOSIS

*Malignant lymphoma, Hodgkin's type*

#### PATHOLOGICAL DISCUSSION

**DR TRACY B MALLORY** An attempt was made to establish the diagnosis by biopsy of a cervical lymph node. That proved fruitless. A group of three small nodes was removed, and they showed only nonspecific, mild lymphoid hyperplasia. Therefore, it was decided that it was justifiable to explore the mediastinal mass, hoping that it might be a tumor that was resectable. The patient was operated on by Dr Richard H Sweet, who found a large tumor lying mostly between the trachea and the superior vena cava. It partially encircled the latter, and although he was able to remove most of the tumor, he could not get all of it. Histologic examination showed a characteristic Hodgkin's disease full of large Reed-Sternberg cells, the largest I have ever seen. There was considerable fibrosis and some tissue infiltration with eosinophils.

## ECONOMIC PROBLEMS OF THE VOLUNTARY HOSPITAL

FIFTEEN years ago, during the height of the depression, voluntary hospitals were confronted with a most critical situation. Private and semiprivate beds were unoccupied, public wards were overcrowded. Philanthropic support was materially affected by general economic conditions, and the voluntary hospitals found themselves in dire straits indeed. As conditions improved, private and semiprivate facilities became increasingly occupied, a fact that demonstrated a willingness on the part of the American public to pay its way in accordance with its financial means.

Today, the voluntary hospital is confronted with an even more critical situation, despite the fact that

hospitals in general are overcrowded as never before, and beds of all types, including private, semiprivate and ward, are in great demand. Hospital income has increased to its highest peak, and yet these institutions are confronted with the largest deficits in their history.

The most important factor in the development of this situation is that operating costs have practically doubled within five years, salaries and wages representing the most substantial factor in the tremendous increase in the per diem cost, with the cost of supplies a close second.

The solution of this problem will be difficult, but it will be found. If the advantages of hospital care are to continue to be available and if the scientific measures that play a part in these increased costs are to continue to be applied, little can be done to reduce expenditures. The answer, therefore, must be found in opportunities for increasing hospital operating income, particularly for the care of patients in need of financial assistance for the payment of the hospital bill.

This brings into focus the importance of reimbursement on the basis of costs from all who are able to pay. It emphasizes the wisdom of insurance protection to meet the expenditures of frequently unpredictable illness. It emphasizes the need for the recognition on the part of governmental agencies of their obligation to reimburse the voluntary hospital on the basis of costs, particularly for those who are considered a public responsibility.

It should be agreed that the voluntary hospital, which concerns itself not only with the care of the sick but also with the training of personnel, the conduct of research and the prevention of disease, is worthy of the increasing and continuing support of everyone in the community who is in a position to give financial assistance.

From the point of view of the patient served, the medical profession should exercise good judgment in limiting admission to patients who are actually in need of "in-bed" care. To hospitalize a person because he is a member of Blue Cross, or even because he can afford to pay for service, is uneconomic, unsound and particularly unwise in that it deprives someone in more urgent need of the opportunity for medical or surgical treatment.

Equally important is the employment of only those diagnostic procedures and therapeutic measures that are essential for diagnosis and treatment. This will save time and money and will play a part in the more regular utilization of a hospital bed.

## TROPICAL DISEASES IN NEW ENGLAND

TROPICAL diseases occasionally invade temperate zones, and the possibility of their occurrence in New England deserves greater emphasis. The report of 2 cases of yaws in this issue of the *Journal* and the recent report of 2 cases of creeping eruption (*Larva migrans*)\* lend added weight to the possibility. Another very recent case of *Larva migrans* infection in a person returning from East Africa, as yet unpublished, further confirms the responsibility of the physician in the matter of tropical disease in New England. These particular diseases are infections that have skin manifestations, they usually occur in warm climates, but the return of military personnel and others from war duty and the rapidity of modern air transportation have increased the risk of transferring to the population of this country certain of the cutaneous diseases, as well as other general diseases ordinarily found in the tropics. The greater volume of travel since the war in the countries to the south of the United States provides additional opportunities for contracting diseases that are endemic in those countries. Tropical and semitropical diseases have been observed with increased frequency along the southern borders, although in the northern third of the country such diseases are still relatively infrequent.

Parasitic diseases of the tropics due to both animal and vegetable parasites and the diseases of bacterial origin, with their complications, will need to be considered in differential diagnosis for some time to come by physicians throughout this area. A carefully taken history, including data about any change of abode or travel, in cases of unusual skin eruptions may be of considerable importance in furnishing a clue to the interpretation of any such manifestation. In the differential diagnosis

of granulomatous lesions and of some of the curious eruptions thought must be given to the possibility of a tropical factor as a causative agent. Moreover, the occasional appearance in this general area of such infections as actinomycosis, blastomycosis, sporotrichosis and tularemia renders it advisable for physicians to be alert to the possibility of these unusual diseases as well.

## RAW MILK AND Q FEVER

SEVERAL times in the past few years attention has been called in these columns to the disease Q fever. At first, this was considered to be an influenza-like disease indigenous to some parts of Australia, where it affected mostly dairy workers and foresters. Interest in the disease in this country was first aroused by the isolation of a rickettsial agent that was identical with *Rickettsia burneti*, the causative agent of Q fever from ticks in many parts of western and southwestern United States, and by the occurrence of occasional cases of infections produced by this agent in Montana.

The first significant infections in this country, however, were observed during an outbreak of laboratory infections at the National Institute of Health in which a rather severe type of atypical pneumonia simulating the viral pneumonias constituted an important part of the clinical picture of the disease. Since that time strains of Q fever have been recognized as the cause of Balkan grippé, of several explosive outbreaks of infections among British and American troops in Italy and the Balkans, and also of additional laboratory outbreaks. In this country circumscribed epidemics of Q fever have been recognized among stockyard and packinghouse workers in Amarillo, Texas, and in Chicago, and serologic evidence of previous infection with this disease among packinghouse workers has recently been uncovered in Fort Worth, Texas.<sup>1</sup>

The most recent findings of interest in this disease have been the occurrence of a number of proved cases of Q fever in the region of Los Angeles, California, and, what is more important, the isolation of the causative rickettsial agent from raw milk in at least four dairies in this region.<sup>2</sup> The isolations of these rickettsias were made from samples of milk studied

\*Lowe, C. U. and Augustine, D. L. Creeping eruption in New England report of two cases. *New Eng J Med* 236 658-661 1947

in three separate laboratories — the Q Fever Laboratory in Los Angeles, the National Institute of Health in Bethesda, Maryland, and the Rocky Mountain Laboratory in Hamilton, Montana

Although the rickettsias were recovered from raw milk, the available epidemiologic evidence did not indicate that the drinking of milk was the cause of the majority of the cases that have been studied thus far. However, it was believed by Huebner and his co-workers<sup>2</sup> that infected milk may serve as a source of infection by some mode as yet undetermined. Proximity to dairies by reason of occupation or residency was a common factor in the histories of more than 50 per cent of the cases in the Los Angeles area. Except for the dairy workers, however, the infected persons rarely used milk from the nearby dairies. Fairly extensive surveys, on the other hand, have revealed that from 10 to 20 per cent of the dairy cows in the Los Angeles area possessed serum antibodies for Q fever, which is strong presumptive evidence of recent infection of these animals with the rickettsia.

The relative ease with which *R. burnetii* was recovered from milk in the Los Angeles dairies suggests a high degree of availability of this pathogenic agent to the human and animal population of that area, since nearly all that milk is transported about the county before processing and much of it is sold raw. The facts that Q-fever infection has been demonstrated in the human population and that a source of the rickettsias of this disease was found to be widely disseminated in the same area suggest a causal relation.

The data, however, do not prove definitely whether or not milk represents an effective source of infection to man. In the outbreaks among packinghouse and stockyard workers and also in some of the laboratory infections a pulmonary route of infection was considered most likely. The same fact may also have been true in outbreaks among troops in the Balkans.

Of additional interest are the studies of a limited number of cows that were shedding *R. burnetii* in their milk. These studies failed to yield the rickettsial agent from whole blood, blood clots, urine or feces. Such findings and the absence of a demonstrable illness in the infected animals suggested that

a local infection of the udder occurs in the absence of concurrent infection in the cow. Furthermore, the presence of these rickettsias was not associated with any observable disease in the udder or with diminution in either the quality or the quantity of the milk. There seems to be no way other than isolation of the rickettsia for recognizing the animals that shed the rickettsia in their milk.

Preliminary studies of the methods of pasteurization of the milk, as practiced in at least two of the large milk plants in the Los Angeles area, indicated that these procedures rendered the naturally infected milk apparently noninfectious, at least for guinea pigs. The residents of Los Angeles will therefore have another potent argument for insisting on pasteurization of their milk.

#### ON SECOND THOUGHT

CONGRESS, on second thought, has reversed its decision to consign the World Health Organization to limbo. The terms on which Uncle Sam is willing to play with the other boys are even being softened. Thus, the House provision that the United States member of the Organization's executive board must have had at least ten years in "active practice" has been reduced to three years' experience in the treatment of patients.

The House has also discarded its insistence that every employee and attaché of this country's delegation must be approved by the Secretary of State. The Senate, not to be outdone in graciousness, has allowed withdrawal notice to be lengthened to a year, instead of the ninety days originally insisted upon by that august body.

#### MASSACHUSETTS MEDICAL SOCIETY

##### DEATH

CROTTY — Martin F. Crotty, M.D., of Cambridge, died on June 5. He was in his fifty-sixth year.

Dr. Crotty received his degree from Boston University School of Medicine in 1924. He was a member of the New England Obstetrical and Gynecological Society and a fellow of the American Medical Association.

His widow survives.

## MEDICOLEGAL ABSTRACT

**Hospitals — Dismissal of nurse at request of physician** In a recent Massachusetts case a registered nurse complained that a doctor had improperly induced a hospital to suspend her right to work at the hospital. There was testimony that it was a valuable business relation for the nurse to have her name on the hospital's call list of nurses and to have the privilege of nursing at the hospital and that the relation afforded her fairly reliable means of access to employment in her profession. The court held that unless the doctor was privileged for some reason he would be liable to a nurse under these circumstances for the harm caused her if he was responsible for her suspension from the hospital. Obviously, a doctor may not obtain a nurse's dismissal solely out of malice or for capricious reasons and without justification.

In this case, however, there was testimony, which the jury may have disbelieved, that a patient of the defendant had told him that the plaintiff had made derogatory remarks about him. These remarks were that he thought he and his patients were the only ones that counted and that he was "a two-cent doctor" and did not know how to take care of his patients. There was also testimony that the defendant had been told that the plaintiff had attempted to take for her patient some bed linen and a blanket intended for the defendant's patient.

Other than the words of the Nightingale Pledge, "With loyalty I will endeavor to aid the physician in his work and devote myself to the welfare of those committed to my care," it appeared that there were no regulations concerning the conduct of the nurses. Their supervision was part of the general administrative duty of the board of management. It was substantially agreed, however, that for a nurse to criticize a doctor to his patient would be a breach of ethics.

The plaintiff testified in effect that she had not made the derogatory remarks about the doctor, that on a prior occasion he had threatened to have her taken off the registry and that the superintendent of the hospital had told her that her name had been taken off the list since he was a very important person in the hospital. The defendant himself contradicted this and testified that he had simply reported to the hospital superintendent what his patient had told him about the conduct and language of the plaintiff, which in his opinion was a breach of ethics, and that he did not request the superintendent to omit the plaintiff or to take her name off the list, but that the superintendent had acted on her own initiative. Both the defendant and the superintendent admitted that the plaintiff was otherwise competent as a nurse and that she would not have been restored to the list until she had seen the defendant.

These conflicts of testimony were for the jury, which found for the plaintiff, to resolve, but in the course of its opinion the court made some interesting remarks about the type of case in which a doctor might be privileged in causing a nurse's dismissal. The court said:

We assume that if the plaintiff did disparage the defendant to his own patient a privileged occasion would arise which would justify the defendant in doing something in relation to the matter for the purpose of maintaining the necessary discipline in the hospital and efficient working relations between nurses and physicians. A privileged occasion of some sort might perhaps arise if the defendant had been credibly informed and believed that the plaintiff had made the statements attributed to her, even if in fact she had not made them. We do not decide these questions.

In any question of privilege the issue is not only whether the doctor was privileged to do what he did but also whether he was privileged to do it as he did. Even assuming that a nurse actually made derogatory statements, the caution of the court's opinion intimates that the doctor's action must be taken "for the purpose of maintaining discipline in the hospital and efficient working relations," and not for the purpose merely of injuring the nurse in her profession, which the jury apparently found was his purpose here, or for other purposes unrelated to the privilege. However, the court thought it unnecessary to consider whether, if the defendant had a privilege of some kind, he exceeded its limits in what he did, or whether the jury could find that he lost any privilege by resort to improper means or that he was so far actuated by express malice that all privilege ceased (*O — v H —*, 1948 *Mass Adv Sheets* 193).

MASSACHUSETTS DEPARTMENT  
OF PUBLIC HEALTHSTUDY OF HEART DISEASE IN  
MASSACHUSETTS

A public-health heart-disease program sponsored jointly by the local boards of health, the Massachusetts Department of Public Health and the United States Public Health Service was endorsed by the Council of the Massachusetts Medical Society at its last meeting. This study is being conducted in an effort to reduce the morbidity and mortality from heart disease in adults, particularly in the productive years. Funds and personnel will be provided by the United States Public Health Service.

The projects have also been endorsed in principle by the New England Heart Association. A technical advisory committee appointed by Dr Vlado A. Getting, commissioner of Public Health, includes Dr Howard B. Sprague, chairman, Dr Edward F. Bland, Dr Laurence B. Ellis, Dr James M. Faulkner, Dr Burton E. Hamilton, Dr Hugh R. Leavell, Dr Samuel A. Levine, Dr Benedict F. Massell, Dr Loren D. Moore, Dr Samuel H.

Proger and Dr David D Rutstein The epidemiologic study of heart disease will be conducted in Framingham in co-operation with the Department of Preventive Medicine of the Harvard Medical School and the Framingham Board of Health with the following objectives to devise and evaluate a method for mass survey of a population for heart disease, to examine a suitable sample of the population to determine the prevalence ratios of various forms of heart disease in the adult groups between twenty and seventy years of age in this area, to carry out a follow-up study to determine the rate at which new cases occur in the population as it ages — that is, the risk of attack — and to observe the natural course of certain forms of cardiovascular disorders, to determine if possible through analysis of data collected the relation of factors such as those of race, heredity, occupation, body build, use of stimulants and diet to the development of heart disease, and to collect records for evaluation of instruments, such as the electrokymograph and photo-fluorograph as case-finding tools

A local professional advisory committee, consisting of T J Carnicelli, M D, Hugh Folsom, M D, H M Levenson, M D, E J DeNicolais, M D, J H McCann, M D, C M Bonzey, Jr, M D, H G Murray, M D, M B Strauss, M D, P B LeBaron, D M D and Mervin Weitz, D M D, will assist in guiding the Framingham program

The heart-demonstration program will be conducted in Newton as a co-operative project with the Newton Health Department, under the immediate supervision of Dr Ernest M Morris, director of public health, with the following objectives to plan and develop in co-operation with the local medical profession and other agencies concerned a public-health program to help meet the increasing problem of heart-disease morbidity and mortality, especially in the productive ages, to prepare a basic manual with information for workers in a public health heart program (the writing of the manual will be supervised and edited by the Technical Advisory Committee)

The local medical advisory committee will participate in the development of the heart-demonstration program, and will consist of members of the public-health committee of the Newton Medical Club These are Drs George Bowers, Theodore Clark and Egon Kattwinkel, with Dr Herbert G Dunphy, president of the club, as *ex-officio* member A committee from the Newton Dental Club is to be appointed

## MISCELLANY

### SAFETY CONFERENCE

One session of the annual Safety Conference, held in April at the Statler Hotel, Boston, was sponsored by the Massachusetts Department of Public Health, Dr Vlado A Getting, commissioner, presiding

Prevention of accidents was the keynote of the afternoon discussion, six speakers emphasizing safety points in their

particular fields Dr Erich Lindemann, of the Massachusetts General Hospital, told of the "accident-proneness" of persons under emotional stress, Miss Frances Frazier, of the Harvard School of Public Health, urged assistance to the aged to prevent falls, and Dr John F Conlin spoke on "The Doctor — Preventive Medicine" Stephen Mahoney, of the Cambridge Recreation Department, stressed the necessity of regular inspection of playground equipment, Mrs Frances Blair, president of the Massachusetts Parent-Teacher Association, spoke on the safety of children, and the concluding speaker, John Chandler, commissioner of agriculture, described the many accidents occurring on the farm.

### BLUE SHIELD FINANCIAL REPORT

The Blue Shield plans of the country, according to a release from the national office in Chicago, recorded a total income of \$48,445,245 during 1947 Of the sum so collected approximately 78 per cent was paid to physicians, 15 per cent went toward operating expenses, and the remainder was added to reserve accounts

### RESEARCH IN SKIN DISEASES

A new and intensive program of research in diseases of the skin was recently announced by Harvard Medical School and the Massachusetts General Hospital The program, financed in part by the Rockefeller Foundation, will bring recent advances in physiology and biochemistry to bear in a search for new knowledge of skin diseases It will be based on close co-operation between dermatologists and experts in general medicine

To develop this new program, Dr Chester North Frazier, head of the Department of Dermatology at the University of Texas, has been appointed Edward Wigglesworth Professor of Dermatology at Harvard University and chief of the Dermatology Service at the Massachusetts General Hospital He will organize a new department of dermatology at the medical school and will lead the research and clinical program at the hospital

## CORRESPONDENCE

### SUGGESTION FOR BETTER PHARMACEUTICAL METHODS

To the Editor A serious problem confronts the medical profession It is becoming more and more apparent that it is the policy of the drug manufacturers to release new drugs as tablets, capsules and ampoules These are all high priced dosage forms The low-cost dosage forms like the powder, which can be used to fill prescriptions that need compounding, and the hypodermic tablet are not available

A drug in point is methadon, which was taken from the Germans in World War II A doctor attending a patient with a gall-bladder attack at night could give an injection of methadon from a hypodermic tablet and then dispense a few such tablets of methadon to be taken by mouth during the night A hypodermic tablet would not cost more than three or four cents However, since the tablet is not obtainable, an ampoule must be used for the injection, at a cost of sixteen cents Then the doctor must have oral tablets of methadon to dispense The hypodermic tablet can be used in two ways and — to make it more pleasant — is much cheaper One must not forget that morphine sulfate has been used in the form of hypodermic tablets for many years, and certainly any of the new drugs can be used likewise

The failure of the drug manufacturers to provide the powder form of drugs is even more serious In the USP (13th edition) I have found that at least twenty of the newer drugs cannot be obtained in the powder form Despite the publicity carried on by drughouses concerning the anti-histaminics, the rank and file of physicians know of many failures with these drugs and would like to combine them in a prescription with ephedrine and aminophylline If the antihistaminic failed, at least the ephedrine and the aminophylline would work in a case of asthma

All physicians should write to the Council on Pharmacy and Chemistry of the American Medical Association urging that steps be taken to make all medicines available in powder form

Brawley, California

BENJAMIN L YELLEN, M D

## BOOK REVIEWS

*A History of Scientific English The story of its evolution based on a study of biomedical terminology* By Edmund Andrews, M.D. 8°, cloth, 342 pp., with 18 illustrations New York: Richard R. Smith, 1947 \$7.50

Dr. Andrews, successful surgeon and erudite philologist, in this outstanding work has produced a history of the origin and transition of scientific language from its beginnings in historic times down to the present. Like some other philologists he believes that all language stems from an unknown ancestor of the prehistoric period. In successive chapters he considers Indo-European philology, semantics and the history of medical terminology. The following chapters discuss various historical aspects, including pre-Hellenic influences, the Aryan heritage, Greek, Latin (including dead or classical Latin), Arabic, French, German and English, divided into Anglo-Saxon, middle and modern. The final chapter deals with the future and advocates Basic English as a common scientific language. A good index concludes the text.

Although Dr. Andrews' book will appeal to comparatively few readers, it should be in all collections of medical and scientific history.

*Emotional Maturity The development and dynamics of personality* By Leon J. Saul, M.A., M.D. 8°, cloth, 358 pp. Philadelphia: J. B. Lippincott Company, 1947 \$5.00

The task of presenting psychodynamic understanding of human motivation that will reach a large and varied group is always a difficult one. In this book, the author presents his material in an extremely readable form. Although his orientation is psychoanalytic, he maintains a conscious oversimplification of the problem, sacrificing completeness and depth for clarity and schematization. He concerns himself with the main motive forces of behavior and personality, accentuating early training and environment but not entirely losing sight of the fundamental biologic drives. He gives considerable attention to the problem of neurosis, illustrating it with numerous well chosen cases.

This book is an excellent primer to the dynamics and development of personality couched in language designed for the layman. It also contains much of interest for those farther advanced in the field of psychiatry.

*Medicine* By A. E. Clark-Kennedy, M.D., F.R.C.P. Volume 1 *The patient and his disease* 8°, cloth, 383 pp. Baltimore: Williams and Wilkins Company, 1947 \$5.00

The author of this work, physician to the London Hospital and dean of its Medical School, rebels against the present-day textbook of medicine, rating it either as a compilation of second-hand facts or as a symposium of disconnected subjects by a panel of writers. This is a harsh and surely contestable evaluation. His own object is to give an account, based on his personal experience as practitioner and teacher, of the nature of the patient and to explain the meaning of his disease, correlating facts rather than enumerating them, and emphasizing the general principles underlying medicine as a whole. As a science medicine deals with the physical aspects of disease as an art it handles all the complexities of the human mind and the many shades of human personality.

Some of the chapter headings in this volume suggest its scope and method: "Body and Mind", "Symptoms and Signs", "Heredit and Environment", "Reactions of the Body and the Mind", and "Nature of Disease". Each chapter has a comprehensive summary.

The following paragraph in the chapter on "The Nature of Disease" exemplifies the author's style and thinking:

The body of man and his mind, at least to some extent, are the product of organic evolution, the result of natural selection of variation in the struggle for existence. Every individual struggles for existence. His genetic endowment may handicap him from the start. Throughout his life he is exposed to all the dangers inherent in the physical world and to competition with other forms of life. There is never-ending competition between man and man. Danger lies in the power of man's will. Adverse factors in heredity and environment act on his body and disturb his mind. All tend to lessen his physical and mental efficiency, and produce pain and suffering. Many shorten his existence and may abruptly terminate his life. Without the power of

adaptation the individual would not survive long and the human race would soon cease to maintain the dominant position which it occupies in the animal world.

It is a work well worth leisurely reading and study.

*Radium Dosage The Manchester System* Edited by W. J. Meredith, M.Sc., F.Inst.P. 8°, cloth, 124 pp., with 38 illustrations, 4 plates and 27 tables. Baltimore: Williams and Wilkins Company, 1947 \$4.50

This publication is an extremely valuable compilation of papers that have appeared in recent years by members of the Holt Radium Institute at Manchester. A method of dosage measurement, correlated with a scheme of distribution giving homogeneity for planar and irregular moulds, cylinders and interstitial radium application, is described simply and lucidly. None of these methods, however, are applicable to the treatment of cancer of the cervix because of the great variation in size, shape and type of the parts and the tissues to be treated. A special chapter is devoted to this subject in which the types of radium applicators advised and the principles underlying their use are described.

Radium has had a much wider use in England than in this country, where, apparently, this therapy has been stymied by the ease with which x-ray dosage may be approximated and phased by the calculations necessary for accurate dosage when radium is employed. Very few clinicians have the type of mentality or the interest to wrestle with the theoretical physics involved in dosage measurement, but welcome data in readily applicable form.

Paterson and Parker, in England, and Quimby, in the United States, have done just that for radium dosage. They have reduced involved formulas to such simple terms that anyone with knowledge of arithmetic can apply them.

The first part of this monograph consists of the clinical aspects of the constituent papers rewritten to form a continuous whole. The purely physical aspects of the work are considered in the second part.

This book should be in the library of every radiologist and radiologic department.

## BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

*Atlas of Bacteriology* By R. Cranston Low, M.D., F.R.C.P.E., F.R.S., member, Bacteriology Department, University of Edinburgh, and consulting physician, Skin Department, Royal Infirmary, Edinburgh, and T. C. Dodds, F.I.M.L.T., F.I.B.P., F.R.P.S., laboratory supervisor, Department of Pathology, University of Edinburgh and lecturer to the Society of Radiographers (Fellowship Course), Scottish Branch. 8°, cloth, 168 pp., with 168 illustrations. Baltimore: Williams and Wilkins Company, 1947 \$5.50

The authors have produced an atlas primarily intended for undergraduate students to supplement class work and standard texts. All the plates except one are in color, and were made from actual color photographs and water-color drawings when it was found impossible to use photographs. Great care was taken to reproduce exact color tones, but unfortunately eight illustrations were reprinted too light in color and because of the shortage of paper could not be reprinted. Each figure shows the magnification, stain and source of culture and notes any other pertinent facts. The color work is good, and the volume well published. The book should prove useful as a ready reference source.

*Applied Medical Bacteriology* By Max S. Marshall, Ph.D. With the collaboration of Janet B. Gunnison, M.A., Alfred S. Lazarus, Ph.D., Elizabeth L. Morrison, M.A., and Marian C. Shevlin, A.B., division of bacteriology, Medical Center of the University of California, San Francisco. 8°, cloth, 340 pp., with 10 illustrations and 12 tables. Philadelphia: Lea and Febiger, 1947 \$4.50

This practical manual has been written for the student, clinician and public-health worker interested in bacteriology.

as applied to his problems. The early chapters have to do with the various technics. These are followed by chapters on viruses, yeasts and molds, biologic products and sanitation. The final chapter, consisting of over half the book, discusses the various diseases due to micro-organisms. These are arranged in alphabetical order, and describe the organism, specimens, microscopical examination, laboratory procedures and reports. The material is well arranged, the text well written, and the volume well published. A good index concludes the volume. An up-to-date list of biologic products and their makers is included.

*Pharmacology and Experimental Therapeutics. A survey for 1941-1946.* By Hamilton H. Anderson, Fumiko Murayama and Benedict E. Abreu. 8°, cloth, 368 pp. Berkeley and Los Angeles: University of California Press, 1947. \$6.50.

In this survey the authors have arranged their material in an alphabetical form obviating the need for an index. The effects of drugs and therapeutic agents are briefly considered, and the references, on which the text is based, are made part of the text. The volume is well published and should prove useful as a reference source in medical libraries and valuable to all persons interested in pharmacology.

*American Medical Research, Past and Present.* By Richard H. Shryock, Ph.D., professor of history and lecturer in medical history, University of Pennsylvania, and acting director, American Council of Learned Societies. 8°, cloth, 350 pp. New York: The Commonwealth Fund, 1947. \$2.50.

Dr. Shryock has written a history of American medical research from its beginning in the middle of the eighteenth century to the present time. The work is divided into twelve chapters, considering in order the formative period of British influence, 1750-1820, early support of research, 1860-1895, the era of private support by foundations and institutions, 1895-1940, research trends, research fields, public relations and public support. The last chapter analyzes the part Government agencies, federal, state and local, have taken in this field since 1940. The text is interesting and well written. Each chapter is documented with references to original sources. There is a good index, and the volume is well published. It should be in all medical, university and general libraries and in historical collections.

*Teaching Psychotherapeutic Medicine. An experimental course for general physicians.* By Walter Bauer, M.D., Douglas D. Bond, M.D., Henry W. Brosin, M.D., Donald W. Hastings, M.D., M. Ralph Kaufman, M.D., John M. Murray, M.D., Thomas A. C. Rennie, M.D., John Romano, M.D., and Harold G. Wolff, M.D. Edited by Helen L. Witmer, Ph.D. With an introductory chapter by Geddes Smith. 8°, cloth, 464 pp. New York: The Commonwealth Fund, 1947. \$3.75.

This book is based on lectures and discussions of the pilot course in psychotherapy in general practice given at the University of Minnesota in 1946, covering a period of two weeks. Nine specialists took part in the presentation of papers and discussions, with illustrative case reports on backache and headache, psychoneuroses, anxiety neuroses, the care of veterans and life situation, emotions and disease. The early chapters deal with general orientation, history-taking, patient-physician relation and normal personality development. Twenty-five physicians took the course, and in addition to the lectures they treated by psychotherapy patients in the outpatient service who suffered from headache, backache, indigestion, vague and persistent pains, fatigue and nervousness. This teaching course was successful from a practical point of view. The volume is well published in every way and is recommended for all medical libraries and should prove valuable to the general practitioner.

*140 Million Patients.* By Carl Malmberg. 12°, paper, 242 pp. New York: Reynal and Hitchcock, 1947. \$2.75.

Mr. Malmberg was formerly information specialist for the United States Public Health Service and chief investigator for the United States Senate Subcommittee on Health and Education. In this volume he advocates the establishment of socialized medicine and the passage of the revised

Wagner-Murray-Dingell Bill, introduced in Congress in May, 1947, as S. 1320 and H.R. 3548. He discusses the subject in five pertinent sections: health inventory of the United States; the cost of sickness; the quality of American medical care; prescription for better health; and voluntary plans—"too little and too late." He concludes with a short chapter entitled, "140 Million Patients Can't Be Wrong."

The author believes that voluntary plans have reached their peak of service and that the Blue Cross has reached the saturation point although the increase in 1947 was 22 per cent over 1946, an increase of over five and a half million new enrollments.

He states that the Taft Bill (S. 545, 80th Cong. First Session) is not constructive but is a delaying action to offset the Wagner-Murray-Dingell Bill.

In the statistical tables of infant and maternal mortality, general mortality and morbidity rates, only countries with a better showing than the United States are listed, those with poorer rates being ignored.

The paper-covered volume is well printed with a good type, on good paper. It should be in all public-health collections.

## NOTICES

### NEW YORK STATE SOCIETY OF ANESTHESIOLOGISTS

The third postgraduate assembly of the New York State Society of Anesthesiologists will be held at the Hotel New Yorker, New York City, on December 9 and 10.

### AMERICAN COLLEGE OF SURGEONS

The thirty-fourth Clinical Congress of the American College of Surgeons will be held in Los Angeles, with headquarters at the Biltmore Hotel, from October 18 to 22. The program of scientific sessions on subjects in the fields of general surgery, eye, ear, nose, and throat surgery, gynecology and obstetrics, urology, and orthopedic, thoracic, plastic and neurologic surgery will be supplemented by operative clinics in hospitals in Los Angeles and vicinity by showings of operations by television and motion pictures, and by a four-day hospital-standardization conference for hospital personnel. There will also be extensive technical and scientific exhibits.

## RETROPUBIC PROSTATECTOMY\*

GEORGE AUSTEN, JR., M.D.,† AND WILLIAM C. QUINBY, M.D.‡

BOSTON

UNTIL recently, time and experience had accepted as satisfactory three principal operative approaches to the prostate: perineal prostatectomy, suprapubic transvesical prostatectomy and transurethral prostatectomy. No single one of these procedures alone is applicable for the treatment of every type of prostatic obstruction. In spite of the contention of surgeons who are strong proponents of one method to the exclusion of the others, it seems fair to say that each of these procedures has certain indications and contraindications, as well as certain limitations and disadvantages, and that each is attended by various technical difficulties that may render the results of operation unsatisfactory. Therefore, when a new and logical method of treatment is proposed, which apparently produces good results in intelligent hands, the progressive surgeon must examine it carefully.

In 1945 Millin,<sup>1</sup> of London, presented his initial report of "a new extravesical technique" of prostatectomy—a suprapubic operation for non-malignant lesions of the prostate to which he applied the name "retropubic prostatectomy." Although Millin considered his operation original, he noted that a somewhat similar suprapubic extravesical approach to the prostate had been made and reported by others. He referred to the reports of van Stockum<sup>2</sup> in 1909 and of Jacobs and Casper<sup>3</sup> in 1933. In both communications there were certain variations in the technic of actual enucleation of the obstructing lobes and closure of the capsule that differed distinctly from the operation described by Millin. He also added that in 1924 Maier<sup>4</sup> reported 4 cases in which the gland was removed by an inguinal extravesical route. However, a review of the literature demonstrates that Millin's report is the first record of any appreciable series of cases treated consistently in this fashion, and it is fair to allow his claim to the

originality and development of the technic that he described.

In his initial publication Millin reported the results obtained in 20 patients with benign prostatic disease who were operated upon by this method, 13 patients had generalized hypertrophy, 2 had fibrous glands with sclerotic bladder neck, 1 had calculous disease, 2 had pure lateral-lobe hypertrophy, 1 had generalized hypertrophy associated with a prostatic abscess, and 1 had post-prostatectomy scarring of the prostatic urethra. There were no postoperative deaths, and complications were few. There were 2 cases of minor delayed bleeding, both in patients who had had grossly infected bladders before operation which was easily controlled by the use of an indwelling catheter for forty-eight hours. No cases of immediate hemorrhage, gross infection, pyelonephritis or renal failure were encountered. A femoral-vein thrombosis developed in 1 case, and an abscess of the testis in another. In only 3 cases was there suprapubic leakage of urine after removal of the urethral catheter on the sixth or seventh postoperative day, and in these cases it was felt that this occurrence was the result of initial faulty adjustment of the catheter. Concerning the long-term follow-up results, Millin believed that it was too early to pass a verdict on the incidence of post-prostatectomy obstruction, but subsequent reports from his clinic<sup>5-7</sup> have shown that postoperative contracture of the vesical neck occurs occasionally. For that reason he has made a modification in his original technic which is described below. However, in summarizing the results in his first 20 cases, Millin stated that "The post-operative comfort has to be seen to be believed." There was apparently very little bleeding into the bladder, catheter irrigations were rarely necessary, and "bladder spasms, so common after the classical prostatectomy," were "absent or minimal."

During the year and a half since the publication of his first report of this new operation, Millin has presented the results obtained by this technic in increasingly larger series of 85 cases<sup>6</sup> and 184 cases<sup>6</sup>. Of his 85 cases, 75 were done in a one-stage and

\*Presented at the annual meeting of the New England Surgical Society, Providence, Rhode Island, October 3, 1947.

†From the Urological Clinic, Peter Bent Brigham Hospital.

§Clinical professor of genitourinary surgery, emeritus, Harvard Medical School.

10 in a two-stage procedure. In the series of 184 cases, approximately 4 per cent had been two-stage procedures. Millin believed that in the future these might form a larger proportion — perhaps 10 per cent. He found no particular difficulty in carrying out a second-stage retropubic prostatectomy when a previous cystostomy had been performed. Although the morbidity and mortality rate for the total series of 184 cases was not recorded, he noted that among his first 85 cases he had had 4 cases of minor hemorrhage and 5 of bladder-neck obstruction due to postoperative stricture or contracture of the vesical outlet. There had been 4 deaths — 2 from pyelonephritis, and 2 from cardiac failure. Since these reports Millin has performed retropubic prostatectomy in more than 400 cases, with a mortality rate of approximately 4 per cent. His experiences with the procedure in this larger group of cases were discussed at the 1947 meeting of the American Urological Association. The operation has been described in the book that he published recently.<sup>7</sup> As a result of his experience to date, he considered retropubic prostatectomy to be "the procedure of choice in every case affording a reasonable operative risk, except for those cases which presented fibrosis and which should have endoscopic resection."

Since Millin's original communication, reports of the results obtained by this operation have been published by other authors in the British medical literature. Although no specific mention has been made of the type of obstruction for which the operation was performed, in the majority of recorded cases the patients apparently had simple benign hypertrophy of the prostate. Series numbering from 3<sup>8</sup> to 63 cases<sup>9</sup> are mentioned. With one exception,<sup>10</sup> all authorities seemed to believe that the procedure had great merit, primarily because of its direct approach to the prostate, avoidance of trauma to the bladder, easy postoperative course with absence of persistent suprapubic leakage of urine, and good functional results. Although the number of patients operated upon by Millin's technic is still relatively small, the death rate and frequency of occurrence of complications in the published cases seem to confirm the optimism of the authors. Jacobs,<sup>9</sup> in a series of 63 cases, had 5 deaths (a mortality of 7.9 per cent), only 2 of which could be attributed to complications directly attendant upon the operation itself. Complications were few and of minor importance. Riches,<sup>12</sup> in commenting upon his results in a series of 40 cases, recorded no deaths. He had 4 postoperative strictures at the vesical neck and 1 case of osteitis pubis. Galbraith<sup>13</sup> noted in his series of 23 cases only 2 minor complications, and Ward<sup>14, 15</sup> reported good results in 7 cases. The principal technical difficulties of the operation mentioned were inability to control bleeding from the periprostatic veins and the possible difficulty of enucleation where

there was much prevesical fat, a deep pelvis and a small prostate. Although no cases of carcinoma of the prostate operated upon by this technic have been noted in the literature, it is reported that Millin himself has performed total prostatectomy through a suprapubic prevesical approach and that the complete removal of the gland was as readily accomplished as simple removal of hypertrophied lobes and fibrosed nodules.

After reviewing the published reports of Millin and others, and as a result of our own experience in attacking the prostate by this approach, we believe that the operation of retropubic prostatectomy, in comparison with the three standard methods of prostatectomy, has the following definite features to recommend it.

The anatomy of the approach is simple and direct, and it presents no important structures that need be sacrificed or organs whose function need be endangered. The dangers of the perineal approach — namely, injury to the external sphincter and rectum — are avoided, and since the procedure is an extravesical one, neither the bladder nor the vesical neck is exposed to the trauma attendant upon the suprapubic transvesical approach.

The exposure of the prostate is excellent, and the entire gland, except for its posterior surface, may be clearly visualized and palpated from the level of the apex below to the level of the bladder neck above.

After enucleation of the hypertrophied lobes, the entire prostatic cavity and vesical outlet may be exposed and examined far more completely than in either of the other standard types of open prostatectomy. Particularly advantageous is the easy control of bleeding, especially that which is prone to occur beneath the posterior vesical lip, and the accessibility of the bladder neck to inspection and any corrective plastic procedures that are found to be necessary. Since the latter structure is not unduly torn or traumatized, as inevitably occurs in the transvesical operation, the intact outlet with its sphincteric action may act immediately after operation as a barrier to the retrograde ooze of blood from the closed prostatic cavity into the bladder and thus prevent to a certain degree much of the postoperative vesical spasm and discomfort often associated with the other types of prostatectomy. Although the exposure is unusually satisfactory, we believe that the Millin operation affords no particular advantage over transurethral resection for the treatment of patients with contracture or sclerosis of the bladder neck except when a plastic procedure is also required.

Reconstruction and repair of the prostatic urethra, with watertight closure of the prostatic

capsule, is easier by this approach than by the other types of prostatectomy. Provided closure of the capsule and fascia is accurately performed in layers and the indwelling catheter is properly adjusted, leakage of urine, which is not infrequent after either perineal or suprapubic transvesical prostatectomy, should rarely occur.

If hemostasis and closure are complete, and urinary leakage avoided, pelvic sepsis is greatly minimized.

In our experience, as in that of others, the most striking feature of the operation is the easy postoperative course for the patient and hospital staff alike. There is very little bleeding into the bladder, and in the majority of cases the urine is clear within twenty-four to thirty-six hours. As a result, frequent irrigations are rarely necessary for more than a few hours after operation and may generally be discontinued except for several cleansing washings daily within twelve to twenty-four hours. There is a variable amount of serosanguineous drainage from the lower angle of the abdominal wound, which may require a change of dressing every eight to ten hours for the first twenty-four to forty-eight hours postoperatively, but thereafter drainage is slight or absent and the incision is usually completely healed in seven to ten days. With no accumulation of blood clots in the bladder and with a dry suprapubic wound after the first few days, the patient has a remarkably comfortable convalescence with little local pain and generally no bladder spasm whatsoever. The use of a small No 20 to 22 Fr Foley balloon catheter minimizes the occurrence of urethritis and any resulting local discomfort. As a rule, the patient is urged to be out of bed on the first day after operation and is ambulatory on the second day.

After removal of the urethral catheter on the fifth to the seventh postoperative day, the patient voids easily and freely, rarely complains of any dysuria and has excellent control of urination. In only 1 case in our series has there been any incontinence, and this was of short duration.

Postoperative urinary sepsis is minimal, and, in contrast to the findings in patients who have undergone transurethral or suprapubic transvesical prostatectomy, a good proportion of cases show a grossly clear urine with little microscopical evidence of infection in the sediment.

In the majority of cases, discharge from the hospital may be accomplished in ten to fourteen days.

In spite of the advantages offered by Millin's operation, the procedure has the following disadvantages, which, at this stage of its development, may be more apparent than real.

The approach may require some time and effort in the adipose patient or in one with an unusually deep and narrow pelvis where the prostate is situated deep at the bottom of a funnel.

In cases in which a previous open cystostomy had been performed, the retropubic approach would probably entail more dissection and trauma than the transvesical method and would thus be less desirable than the latter for a second-stage prostatectomy. We have had no experience with this type of case.

The control of bleeding from the larger vessels in the endopelvic fascia is not always readily accomplished. However, this difficulty is a minor one and should be overcome as the surgeon becomes better acquainted with the operation and the anatomic variations that occur in this region. Hemostasis at this point is greatly facilitated by the use of proper instruments, such as a long-handled needle holder or the boomerang needle, as well as by knowledge of exactly where and how deep to place the transfixing ligatures.

Since the large central vein running longitudinally across the anterior surface of the prostate is in direct communication with the deep dorsal vein of the penis, it has been suggested that ligation and division of this vessel might be followed by edema of the penis. Mild and temporary edema of the penis, which subsided in two or three days, occurred in only 1 case in our series. A similar occurrence of temporary duration has been reported in a few cases by other authors. In view of the extensive anastomotic communications between the veins of the penis and the pudendal plexus, it is difficult to believe that any serious permanent vascular complications of this sort would occur.

When enlargement of the lateral lobes is slight, or when hypertrophy is confined to a subtrigonal or intravesical median lobe, it may be difficult to reach the obstructing tissue with ease. In such cases the outline of the presenting portion of the prostate is hard to define clearly by palpation, and the gland is so mobile that it tends to fall away from the dissecting finger or instrument. This is a disadvantage when one is dealing with the small sclerotic gland or fibrosed vesical neck unless one resorts to the use of a finger in the rectum or a rectal balloon to elevate the gland.

In cases with hypertrophy of the median lobe only, particularly when the enlargement is chiefly intravesical or subtrigonal and is accompanied by excessive fibrosis, enucleation is likely to traumatize and tear the bladder neck. As a result, one of the purposes of the operation — that is, preservation of an intact vesical outlet — is defeated. However, in our experience, this complication has not interfered with a good func-

tional result. When the bladder neck has been torn, one or more simple plicating sutures of catgut will satisfactorily restore the normal anatomy of the outlet.

The approach does not afford adequate visualization of, or ready access to, the posterior aspect of the prostate or its apex in the region of the membranous urethra. Therefore, in cases of early prostatic carcinoma, in which total prostatectomy is indicated, it is our opinion that the prevesical route is much less advantageous than the perineal.

In summarizing the features of the retropubic operation as already outlined, we believe that the Millin technic is particularly suited for treatment of the following types of prostatic disease: benign hypertrophy of the lateral lobes or of lateral lobes and median lobe combined, benign hypertrophy of the median or subtrigonal lobes when intravesical extension is not marked, and calculous disease of the prostate, particularly when associated with benign hypertrophy. With increasing experience and future developments in technic, this approach may also prove to be a good method of performing plastic procedures in the prostatic urethra and at the bladder outlet.

At present we believe that the Millin operation is not indicated for the treatment of patients with obstruction due to sclerosis of the vesical outlet and prostatic fibrosis. In such cases transurethral resection is the preferred procedure. Likewise, in cases of prostatic obstruction associated with disease of the bladder in which surgical therapy of both lesions is required, it is our opinion that some method other than the retropubic approach is indicated. In this category may be grouped patients with prostatic obstruction who also have a vesical tumor, large vesical calculi, a poorly draining diverticulum with or without tumor and any other vesical lesion necessitating surgery. Although small bladder calculi may be removed by the Millin approach without injury to the vesical outlet, stones larger than the intact outlet should be extracted transvesically unless they can be easily crushed and removed transurethrally. For treatment of simple calculous disease or abscess of the prostate without associated benign hypertrophy, the perineal approach is considered preferable to the retropubic one. And finally for the reasons mentioned above, we believe that the retropubic operation is not suited to the treatment of early carcinoma of the prostate.

The actual details of the technic of the retropubic operation, as described by Millin and modified by ourselves and others, will be outlined briefly. After induction of anesthesia, the patient is placed supine on the operating table and in slight Trendelenburg position. If preoperative urethral drainage has been carried out, the bladder is completely

emptied, and the catheter is removed. If the patient has not been on constant urethral drainage, catheterization is performed, and the bladder is evacuated of all residual urine. Failure to comply with this routine immediately prior to operation results in a distended bladder during the operation. As a consequence, the operative field is limited, it is more difficult to expose the prostate adequately, and when the prostatic urethra is opened there is much unnecessary leakage of urine, which not only delays the procedure but also enhances the likelihood of postoperative pelvic sepsis. Subsequent to catheterization, the abdomen, pubes and genitalia are prepared and draped. The penis is covered with a loose sterile towel. A midline suprapubic incision is made, extending from low over the pubis upward for a distance of 10 to 12 cm, depending largely upon the thickness of the abdominal wall and the depth of the bony pelvis. It should be stressed that the lower angle of the abdominal incision must extend well down over the pubis to afford adequate exposure after the self-retaining retractor has been inserted. If the incision is not carried low enough, it later becomes necessary to use an anterior retractor over the pubis to prevent the abdominal wall from obscuring visualization of the depths of the wound. Such a retractor hinders rather than aids the deep dissection. The aponeurosis of the recti is incised longitudinally, the recti are separated in the midline, and the prevesical space is exposed. The prevesical fat and peritoneal fold are then swept upward with finger dissection to expose the anterior surface of the bladder. A self-retaining Balfour retractor with medium-sized curved lateral blades is introduced to keep the edges of the abdominal incision widely separated. Millin advocates the use of a retractor with a self-retaining posterior blade to press the bladder upward and backward, but we have found that by using a broad malleable ribbon retractor, which can be manipulated by an assistant as desired, the exposure is even better. In contrast to the impression of many surgeons that the prostate lies well down beneath the pubic arch, it is surprising how easily and clearly the prostate is exposed in its entirety by this approach. If difficulty in exposure is encountered, gentle upward traction on the bladder accompanied by finger dissection of the fatty tissue surrounding the bladder neck and prostate will bring the entire gland and vesical neck into clear view (Fig. 1).

A variable amount of fatty and areolar tissue lies deep in the retropubic or prevesical space. This is loosely attached to the bladder neck as well as to the anterior and lateral surfaces of the endopelvic fascia which in turn tightly encloses the prostate. By gentle blunt dissection with either a finger or a small swab on the end of a hemostat this tissue may be easily displaced without bleeding except

in an occasional case in which a superficial longitudinal tributary of the pudendal plexus may necessitate ligation. A medium-sized swab or gauze pack, as suggested by Millin, may be pushed into the lateral recess on each side of the prostate to keep the loose fat out of the field as well as to immobilize the gland and control minor venous ooze. The lower portion of the bladder, the vesical neck, and the prostate are clearly exposed, and the distribution of the veins coursing longitudinally across the anterior and lateral aspects of the gland may be noted. These vessels, the prostatic veins, form the prostatic plexus. They lie partly in the fascial sheath of the prostate, the prevesical or endopelvic fascia, and partly between the sheath and the true prostatic capsule. They communicate laterally with the pudendal and vesical plexuses, which in turn drain into the vesical and hypogastric veins. The prostatic veins, as visualized through the retropubic approach, divide themselves into three principal groups, a central longitudinal one whose chief tributary is the deep dorsal vein of the penis and a lateral group on each side of the gland. Anatomic variations are frequent. We have found with increasing experience that the lateral groups of veins generally need not be disturbed. If they are torn during the course of later manipulations, it is a relatively easy matter to clamp them with Kocher clamps and then either transfix and

ligate the ends or fulgurate them with the diathermy. The central vein, on the other hand, lies directly in the path of the capsular incision and must be divided. Prompt and effective control of bleeding from this vessel has been our most harassing problem in the retropubic approach,

and we believe that it is best handled in either one of two fashions. The vessel may be doubly transfixed with deep bites of the needle, ligated and then divided — a boomerang needle or a short, strong, curved needle with a long-handled holder may be used. Or the incision through the endopelvic fascia may be made at once, and the bleeding ends

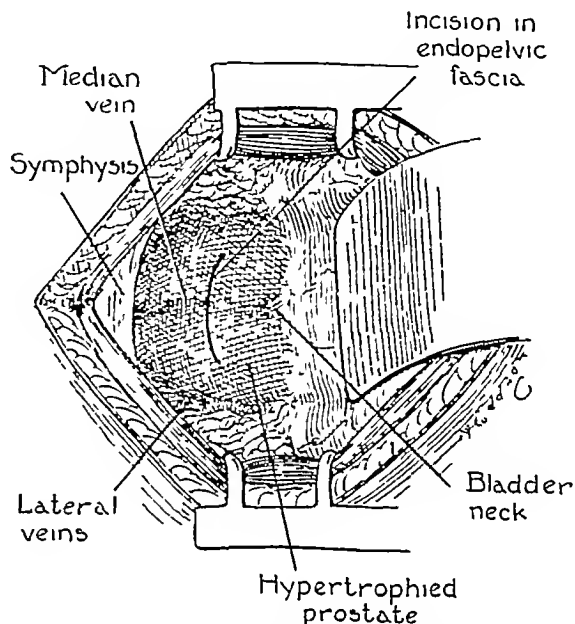

FIGURE 2 Suprapubic View of the Prevesical Space, Showing the Exposure of the Bladder Neck, Prostate and Three Principal Groups of Prostatic Veins, and Illustrating the Site of Incision through the Endopelvic Fascia and True Prostatic Capsule

of the vessel thus exposed are clamped with Kocher hemostats and ligated or fulgured with diathermy. We prefer the former method and have found that in general transfixion and ligation are preferable to the fulgurating current for control of bleeding from this large vessel. Other smaller bleeders can be adequately controlled by diathermy. A 2-cm to 3-cm curved transverse incision, convex downward and approximately 10 to 15 cm distal to the junction of prostate and bladder neck, is made through the endopelvic fascia and true prostatic capsule with a long-handled No. 15 Bard-Parker blade (Fig. 2). Suction is maintained to keep the field dry, and any bleeding vessels in the lips of the capsular incision are grasped with Kocher clamps. With these clamps as tractors the upper and lower flaps are undermined with long dissecting scissors, the upper flap for a distance of not more than 0.5 cm, depending upon the proximity of the incision to the vesical neck, and the lower one for a distance of 1 cm or more, at least for a depth sufficient to expose the lower portion of the gland

except at its very apex. It is often unnecessary to undermine the upper flap at all, since it tends to retract spontaneously during the course of later enucleation. Either the Kocher clamps are touched with the fulgurating current or the vessels are transected and ligated, and the hemostats are then removed. One or two traction sutures of silk are placed in the edge of the upper and lower flaps,

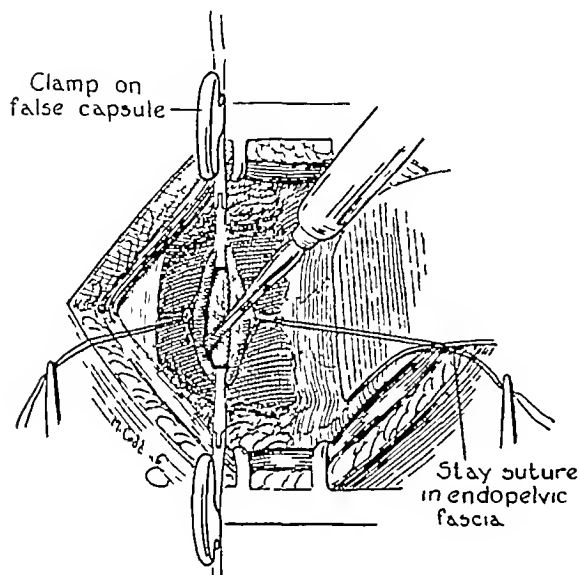

FIGURE 3 The Upper and Lower Flaps of Endopelvic Fascia Have Been Elevated with Traction Sutures, and the Hypertrophied Lateral Lobes Are Exposed through an Inverted V Incision in the False Capsule

and the operator should be able to expose the anterior and part of the lateral aspects of the false capsule for a vertical distance of approximately 2 or 3 cm.

An inverted V incision, with the apex of the V pointing distally in the midline, is made in the false capsule and is carried down to expose the hypertrophied lateral lobes, which are easily recognized by the grayish-white, whorled appearance of the adenomas. If these structures are only slightly enlarged, it is sometimes wiser to continue the incision down into the prostatic urethra. By this means, the line of demarcation between false capsule and adenomas can frequently be more easily recognized. The V-shaped flap is elevated, and a diamond or lozenge-shaped space is opened into which the tip of a finger can be readily inserted. The lateral angles of this incision are grasped with Allis clamps to bring the prostate up toward the operator and at the same time to immobilize it during the course of subsequent enucleation. With a blunt spatula or long curved dissecting scissors the lower lateral margin of the right or left lateral lobe is freed from the false capsule toward the apex

of the gland, and a similar procedure is carried out on the opposite side either then or after one lateral lobe has been more completely exposed (Fig 3). The enucleation of one and then the other lateral lobe is continued with the finger. We have found that the actual digital enucleation is greatly aided by temporary removal of the bladder retractor. The lateral blades of the self-retaining retractor are not disturbed. The lateral lobes having been freed at the apex from below upward, the finger is passed across the midline beneath the distal third of the prostatic urethra, and that structure is then cut with a scalpel or scissors. The severed distal end of the prostatic urethra will retract without bleeding. Lobe forceps are applied to the presenting apical portions of the lateral lobes, and by continued traction and finger dissection posterolaterally from below upward, the lateral lobes, as well as the median lobe when present, are brought up into the capsular wound, being now attached only in the region of the bladder neck (Fig 4). The fibrovascular pedicle of each lateral lobe is clamped with a Kocher hemostat, and the adenomas are detached distal to the clamp with scissors or

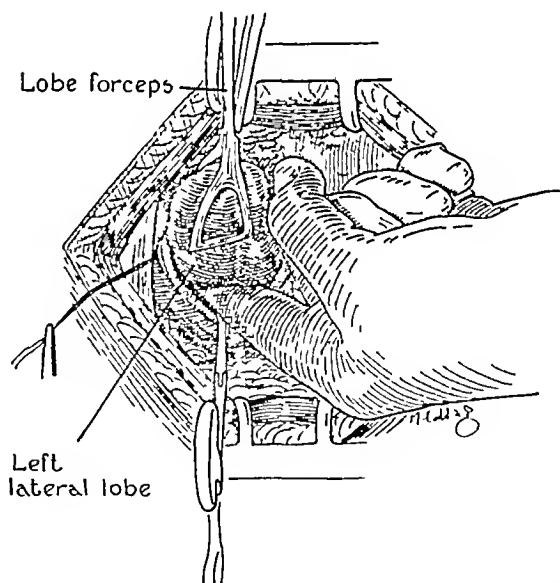

FIGURE 4 The Apexes of the Lateral Lobes Have Been Freed from the Capsule Distally and Posterolaterally, Have Been Grasped with Lobe Forceps and Are Then Enucleated from Below Upward

the scalpel. The median lobe is now enucleated digitally or by sharp dissection from below and behind the floor of the vesical outlet (Fig 5). Any ragged ends of mucous membrane of the proximal urethra or posterior vesical lip are removed cleanly at the bladder outlet with scissors. The pedicles of the lateral lobes are ligated with No. 00 plain catgut, and the hemostats are removed.

In cases in which one is dealing with a sclerotic bladder neck or fibrosed gland or in which the hypertrophy of the lobes is minimal, the technic described above is modified to a certain extent. Since the prostate is small and mobile in such cases, finger enucleation is difficult because the gland tends to fall away from the operator. However, by the application of Allis clamps at the four angles of the capsular incision and by upward lifting of the prostate, the gland is immobilized so that sharp dissection of either small lobes or fibrosed tissue may be performed with relative ease. As suggested above, the use of a rectal balloon or a finger in the rectum to push the prostate upward and forward is of benefit in cases such as these.

The bladder retractor is now replaced, and by traction on Allis forceps secured at the angles of the capsular incision the prostatic bed and vesical outlet are completely exposed to direct inspection. Any bleeders may be seen with ease and are ligated or fulgurated with the coagulating current. By placing an Allis forceps on the edge of the pos-

terior vesical lip, one may lift up the bladder neck and readily control any bleeding in this region, particularly that which may occur from the prostatic arteries in the posterolateral recesses of the prostatic cavity. Furthermore, this exposure allows one to see and remove any tags or small nodules that might otherwise be overlooked. Hemostasis having been completed, the finger is

inserted into and through the bladder outlet. Unless the outlet seems smaller than normal, in which case the vesical neck fits very snugly about the finger, we do not enlarge it. However, if the outlet is snug, a wedge-shaped triangle is removed from its posterior lip with either a punch forcep or the scissors. Minor bleeding in the edges of this wound are easily controlled with the coagulat-

ing current. It should be pointed out that in this operation the bladder neck is normally left intact after enucleation of hypertrophied lobes. It thus hangs free in the upper margin of the prostatic cavity, unsupported by any immediate peripheral attachments and with healing of the wound contracture of the outlet may result. Because of the occurrence of postoperative bladder-neck obstruction in 5 of his first 75 cases, Millin now apparently does a wedge resection almost routinely unless the outlet has been unduly stretched or torn. In the latter event, it is a simple matter to close the outlet to the proper caliber by one or two plicating sutures of No. 00 chromic catgut.

With the prostatic cavity still exposed, a No. 20 to 24 Fr Foley balloon catheter (30-cc capacity) is inserted into the external meatus of the penis and is passed through the urethra into the prostatic cavity. Its tip is grasped with forceps and thereby guided into the bladder (Fig. 6). The balloon is distended with 25 to 30 cc of sterile water or saline solution, and the catheter is then pulled down so that the distended balloon rests lightly against

except at its very apex. It is often unnecessary to undermine the upper flap at all, since it tends to retract spontaneously during the course of later enucleation. Either the Kocher clamps are touched with the fulgurating current or the vessels are transfixed and ligated, and the hemostats are then removed. One or two traction sutures of silk are placed in the edge of the upper and lower flaps,

ing current. It should be pointed out that in this operation the bladder neck is normally left intact after enucleation of hypertrophied lobes. It thus hangs free in the upper margin of the prostatic cavity, unsupported by any immediate peripheral attachments and with healing of the wound contracture of the outlet may result. Because of the occurrence of postoperative bladder-neck obstruction in 5 of his first 75 cases, Millin now apparently does a wedge resection almost routinely unless the outlet has been unduly stretched or torn. In the latter event, it is a simple matter to close the outlet to the proper caliber by one or two plicating sutures of No. 00 chromic catgut.

With the prostatic cavity still exposed, a No. 20 to 24 Fr. Foley balloon catheter (30-cc. capacity) is inserted into the external meatus of the penis and is passed through the urethra into the prostatic cavity. Its tip is grasped with forceps and thereby guided into the bladder (Fig. 6). The balloon is distended with 25 to 30 cc. of sterile water or saline solution, and the catheter is then pulled down so that the distended balloon rests lightly against

the vesical neck. This maneuver not only assures one of the integrity of the balloon but also demonstrates any abnormal disparity between size of balloon and caliber of outlet. A final inspection of the prostatic bed is made. Should oozing be unusual and not controlled by previous ligature or fulguration, the cavity may be packed with fibrin foam or some similar hemostatic agent as described by Quinby<sup>16</sup> and others. We have resorted to this procedure in 7 cases of our series, the wounds in the remaining patients being almost completely dry at the time of closure.

With an assistant steadying the Allis forceps on the margins of the false capsule, the opening in

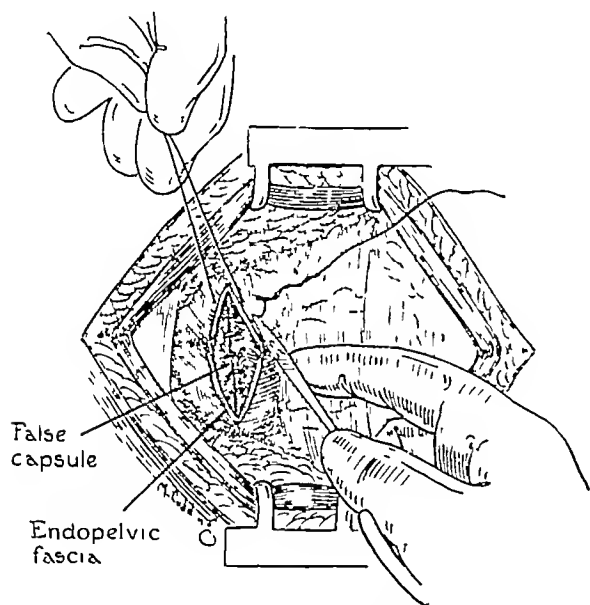

FIGURE 7 *Transverse Closure of the False Capsule and Endopelvic Fascia, Two Layers of Interrupted Sutures Being Used*

this structure, now converted into a more or less transverse one by the stretching subsequent to enucleation, is closed transversely with interrupted sutures of No. 00 chromic catgut. The incision in the true capsule and endopelvic fascia is closed in a similar fashion with fine silk sutures (Fig. 7). The bladder retractor is removed, and the catheter is irrigated with sterile saline solution. If the catheter is properly adjusted and the capsular wound closed tightly, there should be no leakage when irrigation is performed. All swabs and packs are removed, and the prevesical space is irrigated with saline solution and sucked dry to remove clots. An empty Penrose drain is placed down to the suture line in the prostatic fascia and is brought out through the lower angle of the abdominal wound. The self-retaining retractor is removed, and the rectus sheath, the subcutaneous tissue and the skin are approximated with interrupted silk

sutures. A dry sterile dressing is applied. Bilateral vasectomy may be performed either before or after prostatectomy. In our cases vasectomy has not been done, and we have had 2 cases of epididymitis. The catheter is again irrigated to establish its patency, at which time the returns are generally only faintly or moderately blood tinged, and is then connected to a sterile, constant-drainage system.

During the fifteen-month period from June, 1946, to September, 1947, we have treated at the Peter Bent Brigham Hospital 20 cases of prostatic obstruction by the retropubic method of Millin. These cases do not represent a consecutive series. Inasmuch as the method was new and relatively untried, the selection of patients was in general limited to those with a preoperative diagnosis of benign hypertrophy of the prostate without other major complicating diseases of the lower urinary tract. One patient had coexisting bladder calculi, 4 had pathological evidence of associated chronic prostatitis, another had small prostatic calculi in a hyperplastic gland, and 2 were discovered on microscopic examination of the removed specimens to have small previously unsuspected islands of carcinoma in situ. In neither of the last 2 cases was there any evidence of local or distant extension of tumor cells.

The operative risk of the patient, relative to his renal and cardiovascular equilibrium, was not a factor in the choice of these cases for operation by this method. Seven of this group had severe arteriosclerotic heart disease with cardiac arrhythmias or decompensation, while 3 had permanently impaired renal function of mild to moderate degree. On the other hand, the retropubic approach was not chosen for patients with marked intravesical median-lobe hypertrophy, pure fibrosis or contraction of the bladder neck, or prostatic carcinoma.

The ages of the 20 patients varied between 53 and 86 years, with an average age of 70.2 years. The average duration of symptoms of prostatism was 3.65 years. In 2 cases a transurethral resection had been performed for similar symptoms 6 years and 2.5 years respectively prior to the present hospital admission.

Four patients were admitted to the hospital with complete obstruction, 8 had partial retention, and 8 carried only a small amount of residual urine. There was a mild to moderately severe lower-urinary-tract infection in 12 cases, and upon admission to the hospital the blood urea nitrogen was appreciably elevated in 6. In 3 of the latter group the blood urea nitrogen dropped to normal after the institution of drainage, but the other 3 maintained a reading persistently above normal in spite of adequate drainage.

Preoperative drainage of the bladder was effected through a small urethral catheter in 12 cases, the duration of preliminary drainage varying between

6 and 25 days, with an average of 14.4 days. A No 16 Fr Foley catheter with a 5-cc balloon was found to be quite effective, and the drainage was accompanied by very little evidence of local irritation.

The smallest prostate gland weighed 13.5 gm, and the largest 125 gm, the average being 42.1 gm. The majority of glands were the site of trilobar enlargement, the median lobe being of a size equal to or smaller than the lateral lobes. In a few cases hyperplasia was confined to the lateral lobes, the median lobe being normal.

During the performance of the operation, several variations in technic were utilized. In 16 cases a transverse capsular incision was made, whereas in 4 cases a linear incision was used. Although there seemed to be less bleeding from the large prostatic veins with the linear incision digital manipulation during enucleation tends to extend this type of incision too far toward the apex of the gland and toward the vesical neck and thus to render subsequent closure of the capsule and fascia more difficult than when a transverse incision is made. Therefore, a transverse capsular incision is favored. As a result of the later development of contracture of the vesical neck in the first 3 patients upon whom we performed this operation, the bladder outlet was dilated digitally prior to closure in 12 of the remaining cases, and a wedge resection of the posterior lip was performed in 3. Plication of the outlet to reduce it to a normal caliber was performed in 2 cases in which removal of large median or subtrigonal lobes had unduly torn or stretched the vesical neck. One patient with benign hypertrophy, multiple vesical calculi and chronic cystitis underwent a combined retropubic prostatectomy and suprapubic cystotomy with removal of the calculi. Both the urethral and the suprapubic transvesical methods of drainage were used postoperatively. Except in 2 cases in which No 20 Fr and No 26 Fr catheters were used respectively, postoperative urethral drainage was maintained with either a No 22 Fr or a No 24 Fr Foley catheter with a 30-cc balloon.

After operation the urine was clear on inspection within twenty-four hours in 9 cases, within forty-eight hours in 8 cases, and within seventy-two hours in 3 cases. The suprapubic drain was removed, in almost all cases, on the second or third day after operation. In 2 cases in which drainage was negligible the drain was removed twenty-four hours postoperatively. There was generally a moderate amount of serosanguineous ooze from the lower angle of the wound for twenty-four to forty-eight hours, but thereafter drainage was slight, and in the majority of patients the wound was dry and completely healed when the sutures were removed on the sixth or seventh day after operation. The urethral catheter was removed, on the average, slightly over six and a half days

after operation, the shortest period of postoperative drainage being four days and the longest period being nine days. It was necessary to reinsert the catheter in 1 case from the ninth to the thirteenth postoperative day because of a large amount of residual urine secondary to an atonic cord bladder, in another from the tenth to the twelfth day because of bleeding and in a third from the twelfth to the sixteenth day because of suprapubic urinary leakage in a patient who had also undergone a cystotomy for removal of bladder stones. The last patient had a rather severe cystitis before and after operation and was the only one in the series to demonstrate partial incontinence, which persisted until the twenty-eighth day after operation.

Suprapubic leakage of urine occurred in 4 of the 20 cases. In 2 of these, the second and third cases of the series, there was slight drainage from the first to the fourth day postoperatively in 1 and from the sixth to the twelfth day in the other. The cause in both was attributed to faulty adjustment of the urethral catheter and inadequate closure of the prostatic capsule and fascia. A mild wound infection, manifested by local induration and tenderness, was noted in both cases. A third patient, who had vesical calculi and a marked cystitis and was subjected to a combined cystotomy and retropubic prostatectomy, had some leakage of urine from the upper angle of the wound on the tenth to twelfth days after operation. His wound was dry on the thirteenth day after urethral catheter drainage had been reinstituted from the twelfth to the sixteenth postoperative day. The fourth patient, an elderly malnourished man with severe cardiac disease, who had been bedridden for two months prior to hospitalization with chronic cystitis and prostatitis as well as prostatic obstruction, developed an infected hematoma of the prevesical space that was drained on the fifth day after operation. This was followed by suprapubic leakage of urine for a period of three weeks, after which the wound healed spontaneously. With increasing experience regarding proper adjustment of the catheter and watertight closure of the capsule we believe that urinary leakage should rarely occur except in cases in which gross infection of the prevesical space supervenes.

Other postoperative complications in this group of patients were infrequent and relatively unimportant. One patient developed transient edema of the penis on the seventh day after operation. This subsided completely in two days after the application of wet heat and elevation of the organ. Mild unilateral epididymitis occurred in 2 cases, in both of which the infection subsided rapidly with conservative measures. Acute unilateral pyelonephritis on the tenth postoperative day was noted in 1 case. Symptoms and signs abated within thirty-six hours, and the patient was discharged.

from the hospital on the seventeenth day after operation with only a moderate number of pus cells in the urine. Two patients, both of whom had a marked cystitis before operation, continued to show a moderate pyuria during their period of postoperative hospitalization. However, within six to eight weeks after discharge from the hospital, the urine of both patients was free of leukocytes. It is noteworthy that in the majority of our cases the urine was unusually clear after prostatectomy by the retropubic approach.

Immediate postoperative hemorrhage occurred in 1 case, and delayed bleeding of minor degree was encountered in 2. In the first excessive bleeding into the bladder persisted for forty-eight hours after operation, and frequent irrigations were necessary to evacuate clots and maintain satisfactory drainage. Thereafter, bleeding rapidly subsided, and the urine was clear within seventy-two to eighty hours. Another patient, whose catheter was removed on the sixth day after operation, had faintly blood-tinged urine on the following day. There were no accompanying symptoms of irritation or obstruction, and bleeding ceased spontaneously within twelve to eighteen hours. A third patient, in whom the catheter was removed on the seventh day after operation, developed sudden bleeding and clot retention on the tenth postoperative day. The use of an indwelling catheter for forty-eight hours sufficed to control this complication. In none of these cases was urinary infection a contributing factor.

One other complication encountered is that related to proper maintenance of urethral-catheter drainage. In 2 cases the urethral catheter was pulled out of the bladder during the first twelve hours after operation. In both, a faulty balloon was responsible for this event, the bag apparently having burst in 1 case and having developed a slow leak in the other. Fortunately, the accident was discovered promptly before the bladder had become distended, and a new catheter on a stylet was reinserted through the urethra without difficulty. No bleeding or other untoward results followed in either case.

In the 20 cases in this series, 12 patients were discharged from the hospital within eleven to fourteen days after operation, and 6 within fourteen to twenty-one days. One patient was discharged on the thirtieth day, and one on the thirty-third postoperative day. There were no deaths. All the patients have been observed closely since discharge from the hospital, the period of follow-up observation varying between two weeks and fourteen months, 6 patients have been followed for 6 months or more, and 14 have been observed for less than six months. One patient, who had benign hypertrophy and carcinoma in situ, died of coronary thrombosis three months after operation.

Immediately prior to the attack it had been noted that his only urinary symptom was mild nocturia associated with a few leukocytes in the sediment. Post-mortem examination revealed an adequate bladder outlet and no evidence of carcinoma. The remaining 19 patients are living and well. Three of these, the first 3 patients operated upon by the retropubic approach, developed a contracture of the vesical outlet within five to twelve weeks after operation, in 1, acute clot retention followed instrumental urethral investigation five and a half weeks after operation. Suprapubic cystotomy and dilatation of the contracted bladder neck were performed, with an uneventful convalescence. The patient was asymptomatic a year later. The second patient was found to have a stenosed outlet three months postoperatively. Urethral dilatation with sounds was performed on several occasions, and this patient was also asymptomatic ten months later. In the third patient symptoms of bladder irritability and infection appeared shortly after discharge from the hospital. Seven weeks after operation examination revealed a "bar" contracture of the posterior vesical lip and a rather marked cystitis. In spite of prolonged chemotherapy and local treatment in the form of dilatations and irrigation, the symptoms and signs persisted. A recent examination, conducted a year after operation, revealed the presence of a vesical calculus as well as a chronic cystitis and stenosis of the bladder neck. It is planned to perform a transurethral litholapaxy and resection of the outlet on this patient in the near future. A fourth patient, who had a chronic epididymitis preoperatively and an exacerbation of the infection postoperatively, developed a recurrent epididymitis a week after discharge from the hospital. This eventually necessitated orchidectomy several days later, approximately a month after prostatectomy. The remaining 15 patients have had no urologic complaints referable to the operation since discharge from the hospital.

#### SUMMARY

The pertinent literature concerning a newly proposed method of retropubic prostatectomy is briefly reviewed, and the advantages and disadvantages of the procedure are discussed.

The indications and contraindications for the employment of this operative approach are presented in the light of a limited experience with the operation.

The technic of the operation is outlined, and a summary of the results obtained in a selected group of 20 cases is recorded.

## AMEBIC ABSCESS OF THE LIVER\*

### Therapeutic Problems in Various Types of Late Hepatic Amebiasis

EMERSON H. DRAKE, M.D.,† AND THOMAS A. WARTHIN, M.D.‡

WEST ROXBURY, MASSACHUSETTS

THE problem of late complications of disease acquired by military personnel in distant parts of the earth is now facing the medical profession throughout the United States. In all probability it will continue to do so for some years to come. In the six-month period from November 1, 1946, to May 1, 1947, at the Veterans Administration Hospital, West Roxbury, Massachusetts, 6 patients were treated for amebic liver disease secondary to amebiasis acquired while on overseas duty one or two years before. It seems likely that, with the long delay that may take place between the initial infection and the late complication, new cases will continue to appear in areas of the country where the disease is customarily considered as being relatively uncommon. We present these 6 cases, discussing the signs and symptoms, the forms of treatment used, and suggest a plan of treatment that utilizes all aids now currently available.

It has long been known that the high mortality that follows open drainage of an amebic abscess is due to secondary infection entering through the draining site. In 1871 MacLean<sup>1</sup> pointed out that the death rate was lowest in liver abscesses that discharged through the lungs and highest in those draining through the abdominal wall. He advocated the removal of the pus by means of a Bowditch syringe without the admission of air. This method of treatment was abandoned because there was usually a reaccumulation of the material in the abscess cavity, probably owing to the lack of suitable antiamebic chemotherapy. The discovery of the specific effect of injections of emetine by Rogers<sup>2</sup> in 1912 led to a readoption of the closed aspiration method of treatment in conjunction with

the use of emetine to prevent reformation of the abscess. Ochsner and DeBakey<sup>3</sup> reported that in patients treated by open drainage without amebicides the mortality was 48.2 per cent. On open drainage in addition to emetine, the mortality was 16.6 per cent. Of those treated on emetine alone, only 5.4 per cent died. They also stated that in cases in which drainage through a bronchus had already been established, antiamebic treatment was sufficient. Walters et al.<sup>4</sup> recommend that open drainage be reserved for cases in which the abscess cavity obviously has become secondarily infected, or in which rupture into either the pleural or the peritoneal cavity is impending. The latest edition of *Stitt's Diagnosis, Prevention and Treatment of Tropical Diseases*<sup>5</sup> recommends open drainage in a well established abscess. Berne<sup>6</sup> concluded that closed aspiration and emetine treatment reduced the mortality to its lowest level. In the early stages of amebiasis of the liver, Klatskin<sup>7</sup> has clearly shown that repeated courses of emetine alone were sufficient to effect cure.

#### MATERIALS AND METHODS

For discussion of therapy our clinical material is divided into three groups: simple amebic hepatitis, possibly with small abscess formation, a large liver abscess that remained localized within the abdomen, and a large abscess that penetrated through the diaphragm.

Only 1 patient (Case 1) was classified as having diffuse hepatitis without significant abscess formation. He was treated with chemotherapy alone, surgical measures being unnecessary.

Two patients (Cases 2 and 3) had abscesses of significant size that had not drained spontaneously into either the pleural or peritoneal cavities. Both exhibited tender, palpable masses beneath the right costal margin. They were treated by chemotherapy and aspiration. After the institution of emetine therapy, an incision was made in the abdominal

from the hospital on the seventeenth day after operation with only a moderate number of pus cells in the urine. Two patients, both of whom had a marked cystitis before operation, continued to show a moderate pyuria during their period of postoperative hospitalization. However, within six to eight weeks after discharge from the hospital, the urine of both patients was free of leukocytes. It is noteworthy that in the majority of our cases the urine was unusually clear after prostatectomy by the retropubic approach.

Immediate postoperative hemorrhage occurred in 1 case, and delayed bleeding of minor degree was encountered in 2. In the first excessive bleeding into the bladder persisted for forty-eight hours after operation, and frequent irrigations were necessary to evacuate clots and maintain satisfactory drainage. Thereafter, bleeding rapidly subsided, and the urine was clear within seventy-two to eighty hours. Another patient, whose catheter was removed on the sixth day after operation, had faintly blood-tinged urine on the following day. There were no accompanying symptoms of irritation or obstruction, and bleeding ceased spontaneously within twelve to eighteen hours. A third patient, in whom the catheter was removed on the seventh day after operation, developed sudden bleeding and clot retention on the tenth postoperative day. The use of an indwelling catheter for forty-eight hours sufficed to control this complication. In none of these cases was urinary infection a contributing factor.

One other complication encountered is that related to proper maintenance of urethral-catheter drainage. In 2 cases the urethral catheter was pulled out of the bladder during the first twelve hours after operation. In both, a faulty balloon was responsible for this event, the bag apparently having burst in 1 case and having developed a slow leak in the other. Fortunately, the accident was discovered promptly before the bladder had become distended, and a new catheter on a stylet was reinserted through the urethra without difficulty. No bleeding or other untoward results followed in either case.

In the 20 cases in this series, 12 patients were discharged from the hospital within eleven to fourteen days after operation, and 6 within fourteen to twenty-one days. One patient was discharged on the thirtieth day, and one on the thirty-third postoperative day. There were no deaths. All the patients have been observed closely since discharge from the hospital, the period of follow-up observation varying between two weeks and fourteen months, 6 patients have been followed for 6 months or more, and 14 have been observed for less than six months. One patient, who had benign hypertrophy and carcinoma in situ, died of coronary thrombosis three months after operation.

Immediately prior to the attack it had been noted that his only urinary symptom was mild nocturia associated with a few leukocytes in the sediment. Post-mortem examination revealed an adequate bladder outlet and no evidence of carcinoma. The remaining 19 patients are living and well. Three of these, the first 3 patients operated upon by the retropubic approach, developed a contracture of the vesical outlet within five to twelve weeks after operation, in 1, acute clot retention followed in instrumental urethral investigation five and a half weeks after operation. Suprapubic cystotomy and dilatation of the contracted bladder neck were performed, with an uneventful convalescence. The patient was asymptomatic a year later. The second patient was found to have a stenosed outlet three months postoperatively. Urethral dilatation with sounds was performed on several occasions, and this patient was also asymptomatic ten months later. In the third patient symptoms of bladder irritability and infection appeared shortly after discharge from the hospital. Seven weeks after operation examination revealed a "bar" contracture of the posterior vesical lip and a rather marked cystitis. In spite of prolonged chemotherapy and local treatment in the form of dilatations and irrigation, the symptoms and signs persisted. A recent examination, conducted a year after operation, revealed the presence of a vesical calculus as well as a chronic cystitis and stenosis of the bladder neck. It is planned to perform a transurethral litholapaxy and resection of the outlet on this patient in the near future. A fourth patient, who had a chronic epididymitis preoperatively and an exacerbation of the infection postoperatively, developed a recurrent epididymitis a week after discharge from the hospital. This eventually necessitated orchidectomy several days later, approximately a month after prostatectomy. The remaining 15 patients have had no urologic complaints referable to the operation since discharge from the hospital.

#### SUMMARY

The pertinent literature concerning a newly proposed method of retropubic prostatectomy is briefly reviewed, and the advantages and disadvantages of the procedure are discussed.

The indications and contraindications for the employment of this operative approach are presented in the light of a limited experience with the operation.

The technic of the operation is outlined, and a summary of the results obtained in a selected group of 20 cases is recorded.

adherent to the anterior abdominal wall was entered. Over 30 cc. of thick, pinkish-red, purulent material evacuated itself through the incision, and, after irrigation, 200,000 units of penicillin was instilled before the incision was closed. No amebas were found in the pus. The temperature was normal thereafter, and all symptoms rapidly disappeared. Emetine was discontinued after 9 days because of electrocardiographic changes, which proved to be of a temporary nature. A course of vioform was followed immediately by 6 more days of emetine. Changes in the T waves recurred, but on complete bed rest, these were greatly lessened. The patient was discharged on April 2. Follow-up examinations have been negative.

CASE 4 J Z, a 19-year-old veteran, was first admitted to the hospital on August 16, 1946, complaining of right-upper-quadrant pain, chills and fever of 4 days' duration. In 1945 he had had a cystotomy for removal of paraffin, which had been introduced into the bladder through the urethra. From early 1945 to June, 1946, he had been on active duty in Guam and China, but there was no history of dysentery while he was in the service. About 1 week prior to admission he suffered an attack of diarrhea lasting 1 week. Four days before admission he complained of chills and a feeling of oppression in the right anterior portion of the chest and the right upper quadrant. The temperature was 103°F on admission. A tender liver was palpated three fingerbreadths below the right costal margin. Urinalysis revealed a ++ test for albumin and 50 to 60 pus cells per high-power field. The white-cell count was 12,850, with 81 per cent neutrophils. Examination of the stools was negative. Because of acute pain in the right lower quadrant with tenderness and spasm, an exploratory laparotomy was performed on the day after admission. An attempt at liver aspiration yielded no pus, and a fibrotic retrocecal appendix was removed. Postoperatively, on penicillin therapy alone, the high temperature subsided to normal within 7 days. The patient was discharged on the nineteenth postoperative day, entirely asymptomatic.

Five days later he returned, complaining of a chill, which had appeared 2 days prior to readmission, a feeling of discomfort in the right side of the abdomen and a pain in the right shoulder and neck. Physical examination showed some tenderness in the right upper quadrant, with slight voluntary spasm. The temperature was 103°F. A moderate polymorphonuclear leukocytosis was present. The urine was normal. Examination of the stool was again negative for amebas, and a protoscopic examination was negative. Both penicillin and sulfadiazine therapy were begun. On the 17th day the sulfadiazine was stopped because of lack of improvement, and a course of emetine was given. The temperature and white-cell count promptly fell to normal. The emetine was followed by a course of vioform. A retrograde pyelogram was done on September 15 because of urinary symptoms, which revealed a right hydronephrosis and blunting of the pelvic calyces on the right. A culture of the urine from the right kidney grew colon bacilli. After the temperature had been normal for 2 weeks, the patient was discharged to be continued as an outpatient on sulfadiazine.

Two weeks later he was readmitted, having developed a fever 2 days previously, and having coughed up what he thought to be blood. On admission the temperature was 103°F, and the pulse 120. Dullness and absent breath sounds were present in the right axilla and over the right lower portion of the chest anteriorly. The abdomen showed marked tenderness and spasm in the right upper quadrant. The white-cell count was 5400, with 68 per cent neutrophils. Fluoroscopy showed elevation of the anterior mid-portion of the right leaf of the diaphragm, haziness of the diaphragmatic angle and an immobile diaphragm. Penicillin therapy was begun. On the 2nd day he coughed up a considerable amount of thick, reddish sputum in which small trophozoites resembling *E. histolytica* were found. A course of emetine was started immediately. The patient remained acutely ill. On the 6th hospital day an open drainage of a right subdiaphragmatic abscess was performed below the right costal margin. Cultures of the pus obtained were sterile.

Postoperatively the temperature continued to spike. Cultures obtained at subsequent packing of the abscess showed *Staphylococcus albus*. On the 21st postoperative day a second operation was performed, a segment of the seventh

rib in the right anterior axillary line being resected. The temperature at first fell to normal, but again became elevated, leading to the recognition of a supradiaphragmatic abscess pocket, which was drained through the lateral incision on December 23. This left the patient with a small bronchial fistula. The temperature fell to normal, and 18 days later penicillin was stopped.

Twelve days later, profuse purulent drainage, with many motile amebas, again appeared. In addition, a positive culture of *Staph. albus* was obtained. Penicillin was resumed, the drainage wound enlarged, and another course of emetine given. The temperature again fell to normal, and the drainage decreased. A second course of vioform was administered. Gain in weight and improvement in general health continued. The external drainage wound required subsequent revision 2 months later. The patient was discharged on June 27, 1947, after 7 months' hospitalization, with a bronchial fistula, but drainage sites otherwise healed. Subsequent follow-up examination showed closure of the fistula and no further symptoms.

CASE 5 T C, a 34-year-old woolen worker, had been hospitalized with the diagnosis of bacillary dysentery in the Philippine Islands in June, 1945. Hospitalization for right-sided abdominal pain and a high temperature was initiated at this hospital in November, 1945, when tenderness and rigidity in the right upper quadrant were noted. A downhill course, with the appearance of signs over the lower lobe of the right lung, was halted by a single combined course of emetine and penicillin, after which the patient was discharged on January 7, 1946.

He was readmitted late in February for recurrence of the abdominal pain. The findings over the right lower lobe and upper part of the abdomen were again present. The white-cell count was 26,000, and for the first time, typical cysts of *E. histolytica* were found in the stool. Two alternate 8-day courses of emetine and vioform without penicillin were given during the next month without permanent effect. On March 27 under local anesthesia, a trocar was inserted through an incision over the eleventh intercostal space, and 2000 cc of thick, reddish-brown material aspirated. Subsequently the high temperature persisted, the cavity became filled with air, and open drainage was performed on the basis that secondary infection was probably present.

Emetine and penicillin were again administered, with temporary improvement, but the high temperature and profuse drainage promptly reappeared when the therapy was discontinued. In spite of various revisions of the incision, the patient failed markedly, and the wound drained profusely during the next ten weeks, the exudate literally teeming with motile trophozoites of *E. histolytica*. Repeated intramuscular courses of emetine and emetine irrigations did not affect the number of these parasites. Resistance studies of the amebas were performed by Dr. Quentin Geiman, of the Department of Comparative Pathology, Harvard Medical School. Amebas cultured from this patient grew in concentrations of emetine that were much higher than the control strains tested, indicating resistance to the drug in vitro.

On June 25 a thoracotomy with resection of part of the eighth rib was performed, and a pleural empyema cavity with a bronchopleural fistula effectively drained. Disappearance of the trophozoites from the exudate, loss of fever and other improvement occurred from this point on. Convalescence was slow, but the wounds had healed sufficiently for discharge on December 9. Follow-up examinations have shown complete healing of all incisions. During the year of hospitalization the patient received a total dose of 3 gm (45 gr) of emetine intramuscularly without any evidence of toxicity.

CASE 6 J W, a 22-year-old printer, was first admitted to the hospital on December 18, 1946, complaining of fever, cough productive of bloody sputum and pain in the right side of the chest of 2 weeks' duration.

While on overseas duty in Iran during 1944 and 1945, he had suffered two brief bouts of diarrhea not requiring hospitalization. In the month prior to admission to this hospital, 1 year after returning from overseas, he had been hospitalized elsewhere on three occasions for fever of unknown origin. He had been treated with penicillin and

wall to permit, under direct vision, the introduction into the abscess of a large aspirating needle on a syringe. Aspiration was followed by the instillation of penicillin into the abscess cavity and closure of the abdominal wall without drainage. At least one additional course of emetine was administered before discharge from the hospital.

Two of the abscesses that had penetrated through the diaphragm (Cases 4 and 5) were considered to be secondarily infected. These were treated with open drainage.

In another case (Case 6) the abscess had drained spontaneously into the right pleural cavity and through the bronchial tree. The patient was treated with chemotherapy and aspiration of the empyema fluid by thoracentesis.

All patients were treated with intramuscular emetine in a single daily dose of 60 mg (1 gr). The initial course lasted for at least eight days, and subsequent courses were of six days' duration. At least two courses were given to each of the patients. The pulse and blood pressures were recorded three times a day, and electrocardiograms were taken before and on every second day of treatment to determine the existence of drug toxicity. After each course of emetine, all patients received vioform (iodochlorohydroxyquinoline) in oral dosage beginning at 0.25 gm (4 gr) three times daily, and slowly increasing to 1.0 gm (15 gr) three times a day. Dosage at this level was maintained for seven to ten days. Penicillin was injected intramuscularly in doses of 30,000 to 50,000 units every three hours, concurrent with or prior to the initiation of the first course of emetine. It was continued as long as fever or signs of secondary infection were present. The arsenical amebicides were not used.

### CASE REPORTS

**CASE 1** L K, a 25-year-old man, was admitted to the hospital on October 1, 1946, complaining of chills, fever and right-upper-quadrant pain of 7 days' duration. In June, 1945, while serving in the Philippines, he had experienced an intermittent episode of watery diarrhea of 3 weeks' duration, which had subsided spontaneously. Chills and fever due to a malarial infection had been experienced in December, 1945, and April, 1946. One week before admission, while riding in a truck, he had noted sharp, knife-like periumbilical pain, which had later shifted to the right upper quadrant. The pain was aggravated by deep breathing and pressure.

Physical examination revealed the patient to be acutely ill. A tender liver was palpable on inspiration.

The temperature was 102°F, the pulse 100, and the respirations 20.

Examinations of the blood showed white-cell counts of 12,000 to 18,000, with a marked increase in neutrophils. The sedimentation rate was 20 mm per hour. Blood cultures were sterile. Urinalysis was negative. Except for an elevated urobilinogen, routine liver-function tests were within normal limits. After several unsuccessful attempts, typical cysts of *Endamoeba histolytica* were found in the stool. X-ray examination of the chest and fluoroscopy were not remarkable.

The patient ran a daily spiking temperature from 99 to 103°F. On the 4th hospital day penicillin therapy, consisting of 30,000 units intramuscularly every 3 hours, was begun. The temperature was lower on the 7th to 9th days,

but the symptoms remained unchanged. On the 9th hospital day, emetine therapy was instituted, with slow improvement, the temperature falling to near normal by the 3rd day of this treatment. Emetine and penicillin were continued for a total of 10 days without evidence of drug toxicity and were followed by a course of vioform for a similar period. On October 31 and November 2 a high spiking temperature recurred. Thick blood smears revealed *Plasmodium vivax*, and the fever promptly responded to therapy with chloroquin. A second course of emetine was instituted for 6 days after completion of the antimalarial therapy. The patient was discharged November 20, with the diagnoses of amebic hepatitis and malarial fever. During the succeeding month he experienced occasional fever and a constant dull ache in the right upper quadrant. Readmission on December 27, for a third course of emetine and a second course of chloroquin, was followed by the disappearance of all symptoms. When last seen in September, 1947, he was working and in good health.

**CASE 2** W M, a 24-year-old laborer, was first admitted to the hospital on November 30, 1946, complaining of right upper-quadrant pain of 2 days' duration. He had had mild abdominal cramps and watery stools on several occasions while on duty with the United States Army in New Guinea and the Philippines in 1944-1945. He had been evacuated to the United States in 1945 because of skin lesions of the legs and feet. Symptoms had first appeared 2 days before admission, when he had suddenly developed a pressing pain in the right upper quadrant radiating across the back. A temperature of 102°F developed, and he was treated at home with sulfadiazine before being admitted to the hospital. His appetite had remained unaffected.

Physical examination showed moderate tenderness and spasms over a mass in the right upper quadrant. The temperature was 101°F, the pulse 100, and the respirations 25.

The white-cell count was 18,000, with 63 per cent neutrophils. A chest film was normal. It was believed that the diagnosis lay between an acute cholecystitis and an amebic abscess presenting beneath the right costal margin. A preliminary dose of emetine was given, and an exploratory laparotomy performed. The liver was found to be enlarged, the edge extending to the level of the umbilicus. An aspirating needle removed 70 cc. of thick, reddish, purulent material typical of an amebic liver abscess from the right lobe. Penicillin, 50,000 units in 10 cc. of saline solution, was injected into the abscess cavity, and the abdomen was closed without drainage. Smears of the aspirated fluid were negative for amebas, and a culture grew out *Proteus vulgaris*. Postoperatively, penicillin was continued intramuscularly for 19 days. The course of emetine was discontinued after six doses because of changes in the electrocardiogram. The temperature fell to normal on the 4th postoperative day and remained at that level. On December 13 a course of vioform was initiated. On January 6 a second course of emetine was begun, being discontinued after 6 days because of recurrence of the electrocardiographic changes. This was followed by two further courses of vioform and another course of emetine. At no time were amebas found in the stools. The patient was discharged, asymptomatic, on February 4, 1947. He has remained well.

**CASE 3** W K, a 25-year-old musician was admitted to the hospital on February 26, 1947, complaining of sudden onset of fever and a severe, sharp, catching pain across his upper abdomen, increased by cough or pressure. In July, 1945, while serving in the Philippine Islands, he had experienced a severe episode of diarrhea of 10 days' duration, followed by 6 weeks' hospitalization for jaundice and malaria. Loose stools, two or three times a day, and monthly malarial attacks had been noted since 1945.

Physical examination revealed a temperature of 100°F, and a hard, markedly tender liver edge three fingerbreadths below the right costal margin near the midline. There was a moderate polymorphonuclear leukocytosis, and the stools contained numerous actively motile trophozoites of *E. histolytica*. A course of emetine was begun on February 28 and penicillin on March 3. On the following day under nitrous oxide, oxygen and ether anesthesia, a 2.5-cm incision was made over the point of greatest tenderness beneath the right costal margin. An abscess that had become

acute cholecystitis. In others the signs of perihepatitis were outstanding. Restriction of the movement of the adjacent diaphragm without deformity of shape on x-ray examination was often an early sign, and was frequently followed by subsequent pleural involvement.

Laboratory studies in similar types of cases showed the white-cell count to vary from normal to marked elevation. Examination of the stools was positive for amebas in 3 cases, or 50 per cent. Characteristic sputums, after spontaneous drainage of the abscess by hepatobronchial fistula, contained trophozoites in the 2 cases of that group. The exudate from abscess cavities that received inadequate open drainage contained large numbers of motile trophozoites.

#### SUMMARY

Six cases of late amebiasis of the liver are described. None of these patients had previously been diagnosed as having amebiasis. The time of onset of symptoms after returning to the United States from overseas was variable. The onset was usually acute, with signs referable to the liver.

Three problems in therapy are described. These include diffuse hepatitis or small abscesses that heal on chemotherapy alone, large abscesses that require aspiration in addition to chemotherapy — this is most safely performed as a surgical procedure, and large abscesses penetrating above the diaphragm, which may drain spontaneously and be cured by chemotherapy with or without thoracentesis. Occasionally, open drainage may become

necessary, but this should be reserved as a last resort, for it is likely to be followed by prolonged hospitalization.

The best results of chemotherapy were obtained by a combination of emetine and penicillin in two or more courses, alternately with vioform in large doses. Toxic effects of emetine on the heart as revealed by electrocardiogram were noted in 3 cases, but were apparently not serious.

All six patients are alive and well at present, but only a more prolonged follow-up will determine whether or not they have been permanently cured of the disease. The early follow-up study appears to be just as satisfactory in patients treated conservatively as in those treated by radical surgery. The former had a more benign clinical course and a shorter hospital stay than those on whom open drainage was performed.

sulfadiazine, and had received 1 unit of plasma. One week before admission he entered a second hospital with pain in the right side of the chest, a productive cough and fever. A needle aspiration of the right side of the chest revealed fluid typical of an amebic abscess, and he was transferred to this hospital.

The temperature was 101°F, and the pulse 96. There were signs of fluid at the right base, and a tender liver edge was palpable three fingerbreadths below the right costal margin. The white-cell count was 8750, with 56 per cent neutrophils. The stools were negative for amebas, but a sputum examination was positive for trophozoites resembling *E. histolytica*. X-ray study of the chest showed obliteration of the lower two thirds of the right lung field. Aspiration from the right side of the chest yielded 260 cc of sterile bloody fluid containing no identifiable amebas.

Intramuscular penicillin therapy was begun, and a course of intramuscular emetine given. Two subsequent chest aspirations yielded a further 500 cc of fluid. The liver returned to its normal position. On the 12th hospital day the temperature had fallen to normal, where it remained. Penicillin was continued for 26 days, followed by a course of vioform. This was followed by a second course of emetine, which was discontinued after 6 days because of electrocardiographic changes and the development of jaundice. Laboratory studies at that time showed an icteric index of 19, cephalin flocculation of + + + +, a van den Bergh reaction of 2.1 mg per 100 cc, later rising to 5.8 mg (4.2 mg direct, 1.6 mg indirect). This was interpreted as a homologous serum jaundice caused by the plasma received during the previous hospitalization. Over the succeeding month the jaundice cleared, the liver-function tests improved, and the electrocardiogram quickly returned to normal. The patient was discharged, asymptomatic, on March 22, 1947. He was readmitted on April 21, when an x-ray film of the chest, an electrocardiogram, liver-function studies and blood counts were all within normal range. He was discharged without further therapy. Follow-up examinations have been negative.

### Discussion

Patients suffering from diffuse hepatic involvement or from multiple small liver abscesses (as in Case 1) appear to respond well to adequate doses of chemotherapy alone.<sup>7</sup> If an accurate diagnosis can be made and proper treatment instituted, it seems likely that the complications due to penetration of the abscess into the surrounding tissues can be avoided. Single courses of chemotherapy in late larger abscesses proved inadequate. In Cases 4 and 5, if proper diagnoses had been made and adequate treatment instituted at the time of the first admission, it seems probable that many of the subsequent complications would have been prevented.

Needle aspiration of moderate-sized, individual abscess cavities readily localized by physical or x-ray examination, in conjunction with adequate chemotherapy, gave good results in Cases 2 and 3. The period of hospitalization was short, with a relatively benign postoperative course. There was suggestive clinical evidence that penicillin somehow appreciably supplemented the amebicidal action of emetine. No studies in vitro were performed to confirm this impression.

Abscesses draining spontaneously into the bronchial tree may heal on chemotherapy alone, as in Case 6. The presence of a bronchial fistula does not, in itself, necessarily mean that sufficient secondary infection has taken place to require open drain-

age. In the light of subsequent experience we should now treat Case 4 for a longer period with chemotherapy before resorting to open drainage. Similarly, earlier aspiration in Case 5 might have been successful. Patients who had open drainage (Cases 4 and 5) suffered a stormy postoperative course, with a prolonged convalescence. This is in contrast with the results obtained in Case 6 by aspiration and chemotherapy without surgical drainage. Open drainage is indicated only when a thorough trial with chemotherapy and aspiration has proved inadequate. When performed, open drainage must be wide and complete, or repeated drainage procedures will be necessary. In the presence of open drainage and secondary infection, penicillin appears to be beneficial in decreasing systemic reaction and in lessening the quantity of purulent discharge, which is in itself a culture medium for amebas.

All cases should be observed for evidence of emetine toxicity. The electrocardiographic changes were the only ones noted in our series, being present in 3 of the 6 cases. Changes in contour and direction of the T waves in the limb and chest leads were noted in varying degree. They persisted for a few weeks only, were greatly lessened by absolute bed rest and were not associated with tachycardia, arrhythmia, changes in blood pressure or symptoms referable to the heart. The occurrence of such changes in the initial course was not regarded as a contraindication to further courses of emetine. Treatment continued after the development of these changes was not followed by serious effects. This varies considerably with the experience of Dack and Moloshok.<sup>8</sup>

The development of resistance of the parasite to emetine may take place. This was demonstrated by the studies in vitro and the clinical observations in Case 5.

Vioform was found to be an extremely satisfactory means of eradicating the cyst forms. By a gradual increase of the dose to 1.0 gm three times daily, a highly effective intestinal concentration of the drug was attained without producing irritant or toxic symptoms. No parasites were found in stool examinations made during the follow-up studies.

It appears that the primary infection in these cases was acquired while the patients were on overseas duty, 4 having served in the Philippines, 1 in China, and 1 in Iran. Not all had had previous symptoms of intestinal disease, and in none had a diagnosis of amebic dysentery been made. The lapse of time between departure from the overseas duty and the admission to the hospital for hepatic disease varied from two to eighteen months, it can, of course, be much longer.

The onset of symptoms referable to the abscess was often acute and without premonitory symptoms. In 2 cases the physical signs suggested an

The second method may be considered complementary to the first. It consisted of polls inquiring of two types of population groups whether they remembered ever having received tetanus antitoxin. One type consisted of young adults of moderately high economic level, the majority of whom could be said to have medical attention more readily available than the average person. These were the current group of Harvard medical students\*. The information was obtained by checking the routine medical-history forms filled out on admission to the school. The other type of population group was the total adult medical and surgical ward patients of two Massachusetts hospitals. Information was obtained by personal questioning of each patient. In addition to the query about prior tetanus antitoxin, the patients were also asked whether they had ever received a severe burn or a penetrating wound (the example of stepping on a

nail was used) without the administration of tetanus antitoxin.

Similar information on the prevalence of prior inoculation of horse serum (not limited in this series to tetanus antitoxin) was gathered from an article by Lyall and Murdick.<sup>6</sup> In 1000 consecutive cases of accident in which tetanus antitoxin was given, a history of whether or not prior horse serum had been received was obtained from 815 patients. Of these, 110 (13.5 per cent) had had serum before. This percentage is similar to that noted in the ward cases. Both series are definitely significant from the statistical standpoint.

It is thus noted that from 11 to 27 per cent of the general population remember having had antiserum inoculations. In addition, a large number may have received it during the first five or six years of life, when it would rarely be remembered. It is during that time that accidental injuries associated with falling and creeping and often necessitating tetanus antitoxin are especially frequent.

A factor further highlighting the allergic potentialities is brought out in the above series of Lyall and Murdick,<sup>6</sup> many persons receive more than one dose of antitoxin during their lifetime.

For example, the 110 persons mentioned above with a history of prior administration of horse serum were not denied a dose of tetanus antitoxin because of this history. They constitute a portion of the growing group of persons that have had two or more doses of foreign proteins parenterally. Each succeeding dose greatly increases the risk of severe

reactions and anaphylaxis. In the series of 1000 cases referred to,<sup>6</sup> generalized reactions occurred in 23.6 per cent of those giving a history of prior serum injection and in only 8.8 per cent of those without such a history.

Frequency of Injuries that May Result in Tetanus

To estimate the frequency of these injuries it is necessary to arrive at a definite understanding of the types concerned. It has been rather generally believed until recently that penetrating wounds and embedded foreign bodies, especially if contaminated with rural soil, as well as severe burns, accounted for the large majority of cases of tetanus. These wounds, in addition to gunshot wounds and those in which there was considerable maceration

and destruction of tissue, were the ones for which tetanus antitoxin was recommended.

An approximate gauge of the frequency with which this type of wound is remembered can be obtained from Tables 2 and 3, if one assumes that the persons who received tetanus antitoxin did so because of the above type of wound. This is a reasonable assumption, and in the 154 patients personally polled (Table 3) it was corroborated. It is thus noted that approximately 30 per cent of the population can recall such an injury. Again, it is to be expected that many persons had such in-

## DESIRABILITY OF THE ROUTINE USE OF TETANUS TOXOID

EDWARD PRESS, M D , M P H \*

CHICAGO

**D**URING the last few years a considerable amount of additional information regarding the effectiveness and hazards of active immunization against tetanus has become available. The war, with its many casualties among unimmunized, partly immunized and fully immunized civilian and military personnel, contributed greatly to this fund of information. In the light of this added knowledge and in view of the continuing diversity of opinion and practice regarding the routine active immunization of children and adults, it was believed that the entire problem deserved re-evaluation. An effort was made to analyze objectively all the factors involved and to arrive at a definite conclusion whether active immunization as a public-health procedure should be limited to special groups or be administered routinely to all children or adults, or both.

## METHOD

The various factors pro and con are enumerated below and analyzed on the basis of a review of the pertinent available literature supplemented by the following procedures.

A series of 100 consecutive cases of tetanus was culled from the records of five Massachusetts hospitals† and analyzed from the standpoint of the type of injury preceding the disease, the use of prophylactic tetanus antitoxin at the time of the injury and whether recovery occurred. I bear the responsibility for any errors in the presentation and interpretation of these figures.

Pools of two sample population groups were carried out to determine the prevalence of penetrating injuries and the frequency of prophylactic use of tetanus antitoxin.

Personal correspondence with all the private and public laboratories licensed to distribute tetanus antitoxin was carried on to estimate the amount used annually in the United States.

The accident-room records of 250 successive cases of injury in a representative, reputable urban hospital were examined to determine the frequency with which tetanus antitoxin is given and the type of injuries in which it is currently considered indicated.

## FACTORS FAVORING ROUTINE IMMUNIZATION

The factors favoring routine immunization are as follows: the high case mortality in tetanus, the fre-

quency of administration of tetanus antitoxin when active immunization is limited, the marked frequency of accidental injuries that may be precursors of tetanus, the wide distribution of tetanus spores and evidence that they are not limited to soil in rural areas, the allergic reactions to tetanus antitoxin, and the not infrequent failure of tetanus antitoxin prophylactically and the almost universal effectiveness of toxoid.

*High Case Mortality*

In spite of the advent of tetanus antitoxin, sulfonamides and antibiotics, a definitely effective therapeutic agent remains to be found.

In the last twenty to thirty years there has been little, if any, change in the over-all case mortality. The best rate in any statistically significant series is about 35 per cent, and the average is 44.7 per cent (Table 1).

*Frequency of Administration of Tetanus Antitoxin*

To keep the incidence of tetanus low when active immunization is limited, it is necessary to give many doses of tetanus antitoxin. It is obvious that if a sufficiently large number of doses were given, the undesirable effects of this mass sensitization might well overbalance the advantage of omitting routine inoculations of tetanus toxoid.

Two separate methods were used to estimate the frequency of administration of tetanus antitoxin. The first was correspondence with all private and public laboratories licensed to distribute tetanus antitoxin through the Biologics Control Laboratory of the United States Public Health Service. Replies were received from nine out of ten of the private concerns, and annual reports supplemented by correspondence elicited similar figures from all the health departments concerned. From these figures an estimate of the total distributed annually could be made. This would not include tetanus antitoxin packaged for therapeutic use. Undoubtedly, some of this is used prophylactically. It would also exclude any private laboratories whose products were not sold in interstate commerce.

As the replies from many of the private companies were confidential, an individual breakdown could not be given. However, the over-all figures of public and private laboratories amounted to approximately 2,125,000 doses of 1500 units annually, exclusive of returns when the expiration date was exceeded.

study was able to isolate tetanus bacilli from only about half the cultures obtained from wounds (not feces) of 200 patients with clinical tetanus. In the light of this, it is easier to understand the discrepancy in reported investigations. In addition, varying geographic, occupational and sanitation features may be involved.

Table 5 presents a summary of most of the reported studies on this subject.

In the presence of conflicting evidence and a difficult technical procedure, it is reasonable to place more weight on the isolation of tetanus bacilli than on the failure to isolate them. This conclusion is strengthened by the commonly accepted empiric observation that severe burns and wounds with considerable necrosis are likely to result in tetanus if no prophylactic antitoxin is given, regardless of the absence of contamination with rural soil. Study of Table 5 reveals the rather startling fact that tetanus spores are frequently found more often in the feces of human beings than in those of horses.

#### *Allergic Reactions to Tetanus Antitoxin*

In addition to local reactions at the site of injection, generalized allergic reactions, palsies of the peripheral and central nerves and deaths due to anaphylactic shock have repeatedly been described. The incidence of these reactions varies with the purity of the antitoxin, the method of administration, the use of concomitant epinephrine, the criteria of what constitutes a generalized allergic reaction and many other things. It is therefore exceedingly difficult to estimate the frequency of deleterious reactions.

The use of enzyme-digested antitoxins, such as that prepared by Parfentjev,<sup>25</sup> has considerably decreased the number of reactions. Top and Watson<sup>26</sup> believes that this "despeciated" antiserum has reduced allergic reactions—formerly observed in about 40 per cent of cases—to less than 10 per cent in a large number of unselected cases. However, even with the use of these modified serums an irreducible minimum of reactions that is fairly high exists.

#### *Greater Effectiveness of Tetanus Toxoid Prophylactically*

Tetanus antitoxin when given at the time of an injury is usually effective in preventing tetanus. However, to ensure success, it is necessary to continue administering the antitoxin every ten to fourteen days until complete healing has taken place. This is usually not done, and in the majority of cases only a single dose is given, often resulting in a false sense of security. Practically every study of the illness reveals many cases in which tetanus antitoxin failed to prevent tetanus (Table 6). Particularly outstanding is the great number of cases mentioned by Kirschner<sup>28</sup> as occurring in

the German forces in World War I, in spite of the administration of tetanus antitoxin.

Tetanus toxoid when properly and thoroughly administered provides almost complete protection. A review of the experience of the British Expeditionary Forces in the African and European theaters in World War II, presented by Boyd,<sup>27</sup> revealed that only 6 cases of tetanus developed in soldiers who had previously had over three inoculations of tetanus toxoid. In the American experience during the same war on all fronts, including the zone

of interior as well as overseas, Long<sup>29</sup> found that only 12 cases of tetanus had occurred in the entire Army personnel. Of these, only 4 followed both the basic course of toxoid and the stimulating dose, 2 additional cases followed the basic course in which the stimulating dose was omitted. The United States Army procedure for immunization consisted of three 1-cc injections of fluid toxoid at three-week intervals followed by a routine stimulating dose in one year and an "emergency" stimulating dose at the time of injury. The 12 cases in the American Army represent a frequency of 0.44 case per 100,000 wounded (0.22/100,000 if only the immunized are counted). Bruce<sup>5</sup> found that among unprotected personnel about 9 cases of tetanus per 1000 wounded occurred—that is, 900 per 100,000. On the basis of these figures toxoid is over 99.9 per cent effective. Bruce reported an incidence of about 1.12 per 1000 among men protected with prophylactic tetanus antitoxin.

#### FACTORS AGAINST ROUTINE IMMUNIZATION

The factors against routine immunization are as follows: the relative rarity of the disease and the lack of communicability, the availability of antitoxin as a safeguard for injuries customarily causing tetanus, the reactions to tetanus toxoid, the cost of tetanus toxoid, and the possibility of preventing the majority of cases and avoiding in-

juries at too early an age to recall them. Indeed, if splinters are included in penetrating injuries, it is reasonable to believe that the majority of the people have had such episodes.

Recently, evidence has become more prevalent that tetanus very frequently is preceded by non-

\*Information not stated

penetrating wounds and that often a trivial injury results in the disease. Moreover, in a moderately large proportion of the cases, no history of any injury can be obtained. This implies that any wound sustained was so slight that it went unnoted. This concept is not really a new one and has been recognized by a few physicians for many years. In 1923

was the first to place strong, definite emphasis on this point.

Of the 100 consecutive patients with tetanus admitted to the five metropolitan Massachusetts hospitals, 33 had injuries of a nonpenetrating type that were so trivial that medical attention would not have been sought even by the patients in the highest income levels. Examples of this type of injury are infected mosquito or chigger bites, superficial cuts or scratches on the palms, soles, wrist or the dorsum of the hands and slight abrasions of the knee or elbow. In addition, 14 patients in spite of careful questioning could recall no injury whatsoever in the five or six months preceding the onset of the illness.

It is unquestionably true that the vast majority of trivial injuries are not followed by tetanus, and even most of the penetrating wounds might not result in tetanus if unprotected. However in view of the fact that about 50 per cent of the cases of tetanus are preceded by very slight wounds or "no" wounds and the case mortality is about 45 per cent, the conscientious physician would find it difficult to avoid administering tetanus antitoxin in such cases. The problems inherent in such frequent use of tetanus antitoxin are obvious and constitute an excellent point favoring routine use of tetanus toxoid.

#### Wide Distribution of Tetanus Spores

In the majority of cases, medical teaching has transmitted from one textbook to the next the

\*Seven positive specimens were found in 21 soldiers returned from the European Theater.

†No separate test was reported to distinguish toxic from nontoxic strains.

‡Controlled by one specimen from human tissue and not by known positive feces.

Miller<sup>7</sup> stated that it was to be noted that tetanus could come from wounds so slight and so superficial that they were hardly noticeable, and that it was not at all unheard of to have a clear-cut clinical case and yet be unable to find the focus of the disease. Many studies of tetanus reported in the literature reveal no injury or very slight injuries (too slight to implicate a physician) and several of these series are listed in Table 4. Pratt,<sup>8</sup> in 1945,

concept that tetanus spores are generally associated with horses and other grazing animals. More recent investigations using refined anaerobic techniques combined with animal inoculation fail to give uniformly conclusive results. The technique involved is a rather intricate one, and this probably accounts for the difficulty in isolation of the spores from feces and the diversity of the results obtained. For example, Tulloch,<sup>14</sup> in a very detailed and thorough

### *Cost of Tetanus Toxoid*

The cost is the same for both alum-precipitated and fluid toxoid, varying from \$1.12 to \$1.60 per immunizing dose. This is the retail price to the patient. The analogous price of tetanus antitoxin is from 45 to 85 cents. The cost and ease of administration would be reduced if the tetanus toxoid were combined with another toxoid.

### *Limitation of Active Immunization to Specially Susceptible Groups*

If one can assume that the majority of cases of tetanus result from injuries sustained in and around barnyards, ranches and in the proximity of grazing animals, it seems feasible to limit immunization to this group, as well as military personnel. Unfortunately, this assumption is not warranted, as pointed out above.

### SUMMARY AND CONCLUSIONS

An attempt has been made to present impartially the evidence for and against routine active immunization for tetanus. Several of the facts noted are contrary to current general opinion. It was found that about 50 per cent of all injuries leading to tetanus in the civilian population were exceedingly trivial or completely unknown. In addition, it was noted that the majority of bacteriologic studies revealed that tetanus spores were very widely distributed and more frequently found in human feces than in those of horses.

It was noted that the mere presence of tetanus spores in a wound was not sufficient to cause the disease, and the discrepancy between the amount of injuries capable of resulting in tetanus and the number of cases actually occurring was stressed. Several possible explanations for this, including evidence for the existence of a natural immunity, were mentioned.

Statistical evidence was demonstrated to show that less than 20 per cent of the cases of tetanus are reported in the United States. There were at least 910 deaths due to tetanus in the United States in 1940. This compares with 1457 due to diphtheria, 1378 to typhoid fever and 706 to measles.

It was further pointed out that in addition to the number of cases and deaths due to tetanus, one must take into account the number of people sensitized to horse serum by prophylactic tetanus antitoxin as an explanation of the small number of fatal cases. It was estimated that well over two million doses of tetanus antitoxin are given annually and that at least a seventh and probably much more of the entire population receive one or more doses during life. However, if past concepts of proper treatment of injuries are carried out—that is, tetanus antitoxin for penetrating injuries and severe burns—about a third of the population should receive tetanus antitoxin. If present knowl-

edge of the distribution of tetanus spores and the type of injuries associated with the disease were generally publicized, the problem would be greatly intensified. The conscientious physician, aware of the widespread distribution of tetanus spores, knowing the potentiality of tetanus with trivial injuries and being unable to determine which cases might go on to develop it, would be forced to give tetanus antitoxin for nearly all injuries. In view of the definite effectiveness of tetanus toxoid and its almost complete freedom from adverse reactions, its use seems to be indicated.

The not infrequent failure of tetanus antitoxin prophylactically is indicated by the fact that about 7 per cent of civilian and over 50 per cent of military cases developed in spite of its use.

To avoid the increased risk of anaphylaxis and the more frequent allergic reactions to repeated doses of tetanus antitoxin, it is advisable to give toxoid concurrently with each inoculation of tetanus antitoxin. If this active immunization is then completed, it should be unnecessary to use antitoxin for any future injuries in a person by then sensitized to horse serum.

It is my opinion that active immunization against tetanus as a practical public-health measure is indicated. Until further information regarding the pathogenesis of the disease or a simple method of estimating the natural antitoxin level is available, it should be given routinely by private physicians and should also be included in health-department programs for all children. The toxoid should be given to children combined with diphtheria or pertussis vaccine, or both. In addition, children who have been immunized for diphtheria and pertussis, but not for tetanus, should have tetanus toxoid available and be encouraged to use it. Adults with increased accident hazards, such as manual laborers in both rural and urban areas, should also be immunized.

I am indebted to Drs. Stuart S. Stevenson and Carl R. Doering for their advice and suggestions. Particular thanks are due Dr. Harold C. Stuart for his services in helping to make the clinical records available and for general guidance in the study.

discriminate immunization of millions by limitation of active immunization to specially susceptible groups

### *Relative Rarity and Lack of Communicability*

Tetanus is definitely not a common disease in civilian life at present. In 1945 only 439 cases were reported in the United States<sup>30</sup>. Because the illness is not contagious, it can hardly be much of a public-health threat.

In examining these figures more closely, it was found that tetanus was not a reportable disease in four states and that, even in the states in which it was reportable, some cases were not being reported. This could be determined by the fact that more deaths due to tetanus were being reported in some areas than cases. Since death certificates were necessary for burial, this was understandable. Moreover, a large percentage of the deaths due to tetanus followed injuries, and when two or more diagnoses appeared on the death certificate the death was charged to the injury and not to tetanus. According to the *Manual of Joint Causes of Death* whenever tetanus coexists with accidental injuries including burns, cutting or piercing injuries, firearms or abortion, conditions of pregnancy, childbirth or puerperium, the death is not charged to tetanus but to the other cause.

A study by the National Office of Vital Statistics<sup>31</sup> reveals that in 1940 there were 560 certificates recorded in which tetanus was given as the primary cause of death. In an additional 350, it was listed as secondary. This gives a total of 910 tetanus deaths for that year. Assuming the case mortality to be 40 per cent, there should have been 2275 cases in 1940. However, only 411 cases were reported for that year. During the same year, deaths resulting from other diseases for which active immunization is available were diphtheria (1457 cases), whooping cough (2926 cases), typhoid fever (1378 cases) and smallpox 14 cases. As an item of additional interest, it may be noted that there were 706 deaths attributed to measles, 1026 to poliomyelitis and 1725 to acute rheumatic fever.<sup>32</sup>

Another factor opposing routine use of toxoid and related to the relative rarity of the disease is that tetanus fails to follow many injuries that might be expected to cause it. Everyone is familiar with the great many cases in which penetrating wounds or severe burns have failed to result in tetanus in spite of the absence of any precautions. In an attempt to estimate the frequency with which injuries fail to result in tetanus and also the proportion of injuries sustained for which the average well trained physician would give tetanus antitoxin, the following procedure was carried out. The records of 250 consecutive cases of accidental injuries treated in the outpatient department of a reputable metropolitan hospital in Boston were examined. During that time, 20 injuries were treated

with tetanus antitoxin or tetanus toxoid. One hundred lacerated injuries severe enough to require suturing were not given tetanus antitoxin or toxoid, and 130 additional lacerations, abrasions and minor puncture wounds were treated that were not serious enough to merit either suture or any prophylactic measure for tetanus. During, and for an ample time after, this period, no patients with tetanus were admitted to the same hospital for treatment. This experience corroborated the belief that many injuries that are potential precursors of tetanus fail to result in tetanus in spite of the omission of prophylactic measures.

Some experimental work has been done in animals to indicate that the mere presence of tetanus spores in a wound is not sufficient to cause the disease. Other changes of some type are considered to be necessary for the spores to germinate. Space does not permit a detailed description of this work, but among the theories advanced are a change in oxidation-reduction potential of the tissue or tissue necroses, or both, and the presence of ionizable calcium salts.

The large number of human beings harboring tetanus bacilli in their intestines suggests the possibility of circulating antitoxin in the blood stream. This has been corroborated by Tenbroeck and Bauer,<sup>33</sup> who found the antitoxin in about 25 per cent of the persons tested, and also by Van der Reis.<sup>34</sup> This represents another possible factor in explaining the discrepancy between the plentiful distribution of tetanus spores and the scarcity of the disease.

### *Efficiency of Tetanus Antitoxin*

There is ample scientific evidence that tetanus antitoxin, if given repeatedly at intervals of ten to fourteen days from the time of injury until complete healing, will prevent tetanus. This is available in practically every city and village in the United States wherever physicians are located. It does not apply, however, to injuries in which physicians are not in attendance or to those in which physicians do not use it.

### *Reactions to Tetanus Toxoid*

Most of the relatively few adverse generalized allergic reactions were found to be due to Witte and Berna peptones, which were part of the culture mediums commonly used in the preparation of the toxoid. When these were removed, the number of reactions dropped considerably. For example, Long,<sup>35</sup> in a study of about 10,000,000 soldiers, found that the ratio of significant reactions dropped from 46/100,000 to less than 2/100,000. The recently reported crystallization of tetanus toxoid<sup>36</sup> gives promise of a toxoid practically free of any impurities and therefore even less susceptible to allergic reactions.

had no bowel evacuation for 2 days and had expelled very little flatus. Intestinal obstruction was feared, and she was admitted to the New Hampshire Memorial Hospital on December 3. From that time to the day she was operated on for the second time she was treated as a hopeless case. Consultants advised taps and morphine and believed that x-ray therapy would be of no help. The patient was treated accordingly until about June 1, 1942. She was tapped 63 times and from 5000 to 10,000 cc. of fluid removed every 2 or 3 weeks. She was kept comfortable with morphine, the dosage being increased to 30 mg. every 3 hours.

The patient at that time begged to be operated on again, no matter what the outcome might be. The only intention was to explore and insert a mushroom catheter to relieve her of further taps. On June 1 she was operated on at her request. Her weight was about 80 pounds. The abdomen was opened, and there were no peritoneal implants. A fair amount of straw-colored fluid was found. The appearance of the pelvis was altogether different. All the papillary growths were encapsulated in one large mass to the left and two other smaller ones to the right. All were adherent to the adjacent organs, rectum, uterus and bladder. The growths were dissected and removed with great difficulty except for a small portion about the size of a silver dollar in the right fossa. Some of the contents were spilled in the abdominal cavity and removed with care. The uterus was not removed because of the difficult and long operation. One mushroom drain was left in place, and the abdomen was closed in the usual way.

The pathological diagnosis was papillary cystadenocarcinoma of both ovaries (Fig. 1), with extension to the peritoneum.

The postoperative recovery was fair and rather stormy because the patient was deprived of morphine. She was given two 500-cc. transfusions. The drain was removed on June 27. The abdomen was not healed before September 12, and until that time the temperature went as high as 102°F. The patient was then transferred to the medical service. She improved, gradually gained weight and was discharged November 22, after having spent 1086 days in the hospital.

The patient has been checked regularly every 6 months. She had one scant menstrual period and occasional hot flashes after the second operation. She was checked for the last time 2 months ago, with no apparent recurrence. Her weight is now 140 pounds, she feels well and works every day.

When Dr. George Van S. Smith, of Brookline, Massachusetts, was told about this case in 1946, he thought that there might have been an error in the pathological diagnosis, but after studying the slides himself, he was convinced that the diagnosis was correct and that the case was out of the ordinary and difficult to understand and explain.

#### SUMMARY

Papillary cystadenocarcinoma of the ovary is a malignant epithelial growth. The prognosis is very poor. Early diagnosis is essential, and treatment

should be as radical as circumstances permit, followed by x-ray therapy.

A case of papillary cystadenocarcinoma of the ovary, diagnosed approximately one year after the onset of symptoms, is reported. The patient

FIGURE 1 Photomicrograph of Section of Ovary, Showing Papillary Cystadenocarcinoma

had actual surgical, but not radical, treatment four years after the onset of symptoms and without postoperative x-ray therapy. Yet after more than eight years she feels well, works every day and is apparently cured.

## PAPILLARY CYSTADENOCARCINOMA OF BOTH OVARIES

### Report of a Case with Apparent Cure Eight Years after Operation

GERARD L. GAUDRAULT, M.D.\*

CONCORD, NEW HAMPSHIRE

THE following case appears to be one of those mysterious cases that cannot be explained. After reading textbooks and journals I came to the conclusions that the patient had had actual surgical treatment four years after the onset of symptoms, that she had not been given x-ray therapy and that a hysterectomy had not been performed.

Meigs<sup>1</sup> states that cancer of the ovary of the malignant papillary cystadenoma type is about as malignant as any other epithelial growth and that bilateral oophorectomy and hysterectomy are the proper treatment. Jones<sup>2</sup> reported 30 cases of papillary cystadenoma of the ovary and stated that the prognosis is extremely poor. Another authority, Pemberton,<sup>3</sup> writes that cancer of the ovary should be treated by as radical an operation as circumstances permit, followed by x-ray therapy. The results of treatment are poor, and early diagnosis is essential.

Curtis<sup>4</sup> states that prognosis with frank carcinoma of the ovary is not good. Five-year salvage is obtained in 60 per cent of the patients with unilateral growths and in 20 per cent of those with cancer of both ovaries, but this includes many small early cancers discovered at operation and cases with slowly developing tumors and relatively benign peritoneal implants.

The comments of other authorities indicate that upon the advent of such symptoms as discomfort,

pain or free fluid in the abdomen, the patient is very seriously handicapped and that the chances of recovery are extremely poor.

A S., a 26-year-old housewife, entered the Margaret Pillsbury General Hospital on November 7, 1939, complaining of discomfort in the lower abdomen, distention, menstrual irregularity and loss of weight, as well as pain in the lumbar region and legs.

The past and family histories were irrelevant. The patient was married, and her husband was well. She had had no pregnancies. For 1 year prior to admission she had complained of some discomfort in the lower abdomen, back and legs. During the last 2 months before admission the discomfort increased markedly, and since other distressing symptoms appeared, admission was advised.

Physical examination showed the patient to be pale and cachectic. The abdomen was distended and tender, and on percussion the presence of fluid was detected. No masses were felt. Pelvic examination revealed a small uterus in normal position, not movable, and a tender, diffuse mass in the pelvis. A tentative diagnosis of tuberculous peritonitis or adenocarcinoma was made.

Examinations of the blood were within normal limits. The urine showed a trace of albumin, sugar and acetone.

On November 9 a laparotomy was performed, and about 2 liters of straw-colored fluid drained from the abdominal cavity. Exploration of the pelvic cavity revealed a small uterus in good position and large papillary growths of both ovaries, with extensive papillary peritoneal implants in the entire pelvic cavity.

Three other physicians were called in for advice, and it was decided that the disease was too extensive and advanced for surgery to be of any benefit. A biopsy was taken, and the abdomen was closed.

The pathologist reported metastases of a papillary cystadenocarcinoma of the ovary. The patient was discharged on November 22, still complaining of some abdominal discomfort.

On December 2 the patient was seen at home. She complained of severe abdominal distress and distention, she had

\*Chief of obstetric and gynecologic staff, Concord Hospital.

need for therapeutic malaria. This belief has not been substantiated by results of extensive series of treatments using penicillin alone.<sup>61</sup>

The mode of action of malaria therapy and of penicillin on *Treponema pallidum* is not known. Since penicillin has no effect on either malarial parasites or clinical malaria, malarial and penicillin therapy either given simultaneously or in sequence have been used extensively.<sup>61</sup> That these procedures will continue to be utilized for some time is entirely possible in view of the 5 per cent increase of syphilis reported for the first half of 1947<sup>61</sup> and the expected subsequent increase in neurosyphilis. Thus, a brief review of procedures for handling therapeutic malaria is warranted.

The infection of choice for therapy of white patients is *P. vivax*. Various strains, such as the McCoy, St. Elizabeth's<sup>62</sup> and Chesson's,<sup>63, 64</sup> are generally available for therapy. Except for the use of infected anopheline mosquitoes to produce experimental infections, the infection is induced in man by passage of 2 to 5 cc of infected blood, and the incubation period, depending on dosage, is approximately two to six days. Wherever reliable parasite counts can be obtained, definite dosages give more consistent incubation periods and predictable course of infection. Kaplan et al.<sup>65</sup> recommend a dosage of 1,000,000 *P. vivax* parasites for susceptible white patients. In our experience with the McCoy and St. Elizabeth's strains,<sup>66</sup> a dosage of 500,000 parasites per kilogram of body weight gives desirable results. There is also evidence that the compatibility of the parasitized blood to be inoculated affects the incubation period. When compatible blood is used the incubation period is approximately two days shorter.<sup>64</sup> The determination of parasite densities during the infection helps also to predict onset, clinical course and spontaneous control of parasitemia.

American Negroes have varying degrees of natural resistance to certain but not all strains of benign tertian malaria.<sup>67</sup> Hence, if Negroes fail to develop clinical malaria after inoculation with *P. vivax*, quartan malaria (*P. malariae*) should be used to obtain the desired hyperpyrexia. If available, the latter species should be the original organism of choice for Negroes. This infection has some disadvantages, such as a longer incubation period (given variously as twelve to fifteen days<sup>68</sup> in a series of 92 patients and as an average of slightly over nineteen days in a series of 38 patients<sup>69</sup>) and intervals of seventy-two hours between paroxysms. These characteristics lengthen the time of hospitalization considerably and tend to eliminate the use of quartan infection in other than resistant Negroes and white patients.

*P. falciparum* of malignant tertian malaria is considered too dangerous for use in treating paretics without laboratory control. This type of malaria is less severe in Negroes than in white patients,

and it can be used to obtain hyperpyrexia without great risk if the parasitemia is not allowed to exceed approximately 100,000 per cubic millimeter. If this infection is used in paretics, parasite densities should be determined at least twice a day because of the rapidity of multiplication of the parasite during the primary attack.

In numerous hospitals, the supply of paretics is not great enough to ensure continuous passage of malaria. Since infected blood loses its viability within two weeks when stored at ordinary refrigerator temperatures, the problem of keeping and obtaining infected blood for new patients constantly arises. The technic of using low-temperature freezing to preserve human malarial parasites has been developed.<sup>66, 70</sup> The method was originally devised for the preservation of simian and avian plasmodia.<sup>29, 71, 72</sup> If a dry-ice cabinet or a mechanical deep freeze is available to maintain the temperatures below  $-50^{\circ}\text{C}$  infected blood containing *P. vivax* or *P. falciparum* can be frozen and stored for lengths of time up to at least six months. Attempts have been unsuccessful with *P. malariae*. One or two cubic centimeters of the infected blood is sealed in thin-walled, 5-cc vials or ampoules and frozen quickly by twirling of the vials in a bath of alcohol precooled to  $-50^{\circ}\text{C}$  or below or in a bath of dry ice and alcohol at a similar temperature. At no time should the temperature of the stored blood be allowed to rise above  $-50^{\circ}\text{C}$ . In use, the vials of infected blood are transported from the storage cabinet in a bath of alcohol and dry ice ( $-50$  to  $-70^{\circ}\text{C}$ ) to the bedside where it is to be used. The vials of blood are thawed quickly in water at  $37^{\circ}\text{C}$ , a syringe is filled, and the blood is injected immediately. Two to five cubic centimeters of thawed blood has been injected without any reaction. In our laboratory, at the Department of Comparative Pathology and Tropical Medicine, Harvard Medical School, where human and simian parasites are maintained constantly in a deep-freeze, best results have been obtained with blood taken during the last half of the cycle before a paroxysm, when the parasites are half or full grown. Sterile precautions and sterile equipment must be used throughout the procedure.

In the previous review,<sup>1</sup> the use of thiobismol was discussed as an aid in inhibiting one of the paroxysms in debilitated patients who have daily rises in temperature during *P. vivax* infections. Many inquiries have been received about this procedure. When the directions for its use as recommended by Young, McLendon and Smarr<sup>73</sup> are followed, desired results are obtainable. But when thiobismol is injected at the wrong part of the parasite cycle, the results are disappointing. No information is available about the exact mode of action of this drug on *P. vivax*, but it is known that the half-grown parasites or trophozoites are affected. Thus to derive maximum effects, 0.1 to 0.2 gm

## MEDICAL PROGRESS

### MALARIA (Concluded)\*

QUENTIN M. GEIMAN, PH.D. †

BOSTON

#### TRANSFUSION MALARIA

Unexpected clinical malaria has occurred in many nonendemic malarious areas when patients receive transfusions of blood from donors who had previously lived or had been exposed to infection in endemic malarious areas<sup>54-58</sup>. In New England the majority of such cases of transfusion malaria before World War II resulted from transfusions from adults who had previously lived in the Mediterranean area. With few exceptions, quartan malaria was the type that was contracted by the recipients of such donor blood. Rubenstein et al.<sup>59</sup> recorded some of these cases, which were reported to the Massachusetts Department of Public Health. In the list of cases, only two of the twelve infections were caused by *Plasmodium vivax*. With the exception of one unidentified case, the other cases were definitely identified as quartan malaria.

The basic reason for the incidence of quartan malaria among these cases resulting from transfusion is the long-lived latency of this type of malaria. This characteristic is not typical of *P. vivax* or of *P. falciparum*.

Two results of World War II and increasing air travel to tropical areas have tended to focus attention on this problem of transfusion malaria. In the first place, relatively great numbers of men were stationed at one time or another during World War II in endemic or hyperendemic malaria areas. In the second place, blood banks have been organized at hospitals for transfusion purposes. This blood is stored for varying periods up to two weeks before it is used.

Although very little quartan malaria occurred in the armed forces during World War II, the high incidence of *P. vivax* and *P. falciparum* prompted a review of the danger involved in using blood from such persons after they have had malaria. *P. falciparum* is not a seriously relapsing type of malaria, and it tends to be cured or to stop spontaneously within a year after the initial infection, provided there is no reinfection or transmission by mosquitoes. On the other hand, the vivax malaria that occurred among the forces in the Pacific theater of war was a seriously relapsing type. There are still a number of these men who continue to have relapses although they had their initial infection two to four

years previously. Available records show that vivax malaria seldom persists beyond three to six years after the initial infection. Thus, blood for transfusion purposes should be refused even in cases of emergency from persons who have given a previous history of any type of malaria. If the species causing the previous infection were known, this statement could be modified, but the intended donor seldom knows more than that he had malaria. It must be realized that the blood during the intervals between relapses of vivax malaria is infective and should not be used for direct transfusion or for storage in blood banks. There is no reason, however, to exclude persons with a previous history of malaria from giving blood for the production of plasma.<sup>60</sup> The parasites live within the red cells, and these cells are discarded during the processing of the plasma for therapeutic use.

The incubation period for transfusion malaria depends upon the numbers of parasites present in the donor's blood and the species of plasmodium. The incubation of quartan malaria as passed by inoculation of infected blood to paretics ranges from one to four weeks. Thus, with submicroscopic parasitemia existing in latent malaria, the incubation period might be as long as three months. This is not so, however, with *P. vivax* from patients who have had relapses of tertian malaria within a few months. In these cases, there are greater numbers of circulating parasites and hence the incubation period in the recipient would be five to fourteen days.

Thus, it should be emphasized that donors of blood for transfusion or for the replenishment of supplies in the blood bank should be asked about a previous history of malaria. If they have had malaria at any time in the past or recall symptoms that might have been due to malaria, their blood should be refused. Their blood can be used, as stated above, for the production of plasma.

#### INDUCED MALARIA

The paradox of using one disease therapeutically to treat another exists in the practice of using human malaria to obtain hyperpyrexia in patients with paresis or neurosyphilis. This therapeutic procedure dates from the successful experiments of Wagner-Jauregg in 1917.<sup>48</sup> The effects of hyperpyrexia produced by induced malaria, mechanical fever cabinets or typhoid vaccines in the hands of many clinicians appear to favor the use of malaria.

The discovery of penicillin, however, and its efficiency in the treatment of paresis was originally believed sufficient to supersede and eliminate the

†Assistant professor of tropical diseases, Harvard Medical School.

"to have more meaning than that based on plasma concentration"

Studies by another research unit of the Army<sup>51</sup> tend to oppose this view. This group determined the range of plasma concentrations, obtained in a group of men on various dosage schedules, concentrations after completion and after interruption of drug courses, the variation of concentration in persons on the same schedule, the influence of environment on the plasma concentration and the toxicity of the drug. The important results for this discussion are the wide variations of plasma concentrations obtainable in a group on the same dosage schedule and the relative nontoxicity of the drug.

Fairley and his collaborators<sup>52</sup> in Australia studied the build-up, equilibrium level and die-away concentrations of quinacrine after certain dosage schedules, and the effect of such levels on suppression and clinical and radical cure of benign tertian and malignant tertian malaria. These studies established the fact that quinacrine in a dosage of 0.1 gm (1½ gr) daily suppressed falciparum malaria. When the dosage was continued for a required period of approximately a month after the last exposure to infection, a radical cure was obtained. The dosage schedule, furthermore, suppressed benign tertian malaria, but clinical malaria will develop at varying intervals of a few days up to a year<sup>53</sup> after the drug has been discontinued. The prophylactic or suppressive dosage for adults is as follows: one tablet of 0.1 gm (1½ gr) daily, preferably beginning two weeks in advance of exposure, and continuing for at least four weeks after the last possible exposure in a malarious area.<sup>54</sup> When quinacrine is to be taken as an antimalarial drug, administration should be started up to two weeks before a malarious area is entered. This procedure is essential to get an effective plasma level for suppression of clinical malaria.

The thorough review of toxicity of this antimalarial agent by Findlay<sup>54</sup> deserves comment. A comprehensive reference list was covered to record the severe toxic reactions associated with quinacrine therapy before and during the war. This paper should be read by those passing on claims for compensation or pension by persons who have a history of toxic effects following quinacrine therapy.

The primary toxic reactions to quinacrine involved the skin, central nervous system, hematopoietic system and eyes. Lichenoid dermatitis contracted by American and Australian troops in the Pacific area is considered in detail. The incidence of toxic psychoses, frequently exaggerated during the war, was found to be quite low. In a collected series of 89,168 persons receiving quinacrine, 126 developed psychotic symptoms. Unique corneal lesions are described that developed in a small series of industrial workers handling the drug in

quantity and in persons taking large doses of the drug.

The author emphasizes the fact that "hundreds of thousands of persons in the services were given quinacrine without ill effects."

### *Chloroquine*

Another compound, chloroquine diphosphate (synonyms, SN-7618, resochin and aralen) has been found to be a more potent antimalarial drug than quinacrine.<sup>55</sup> This compound—7-chloro-4-(4-diethylamino-1-methylbutylamino) quinoline diphosphate—was first synthesized and patented in Germany.<sup>56</sup> Two years later the patent granted in this country was assigned to Winthrop Chemical Company. During the North African Campaign, sontochin (SN-6911), a relative of chloroquine, was captured from the Germans, who were using it against malaria. This led to an extensive investigation of both drugs in this country.

Surrey and Hammer<sup>57</sup> synthesized samples of chloroquine and sontochin for testing, and additional samples were synthesized later by "several University laboratories under OSRD contract."<sup>58, 56</sup> Screening tests with avian malaria and extensive pharmacologic, clinical and field tests showed that both drugs had valuable antimalarial properties but that chloroquine was superior, with approximately the same antimalarial properties as quinacrine. The rapidity of absorption and lesser localization of chloroquine in tissues and organs contributed to the greater potency on lower dosage schedules and hence with lower plasma concentrations. One dose of chloroquine per week (0.5 gm) will suppress *P. vivax* and *P. falciparum* infections, and clinical malaria can be treated successfully in three to five days. Furthermore, the drug does not lead to discoloration of the skin. The toxic symptoms developing from therapeutic dosages parallel those of quinacrine. Mild and transient headache, visual disturbances, pruritus and gastrointestinal disturbances are the most common complaints. In the words of Loeb et al.,<sup>58</sup> "none of these manifestations have been constitutionally serious and all have been readily reversible."

Most and his associates<sup>58</sup> treated more than 1000 cases of acute vivax malaria, and compared the control of symptoms and toxicity by quinine, quinacrine and chloroquine. As might have been expected, each drug gave different results, but in general chloroquine controlled fever more quickly, reduced the parasitemia faster, lengthened the interval between relapses and gave less toxic symptoms.

Chloroquine will effect a complete cure of malignant tertian malaria. When taken prophylactically, this drug will not prevent infection, but it is effective as a suppressive. Clinical cures of vivax malaria are readily obtained, but relapses are not prevented.

of the drug is injected intramuscularly sixteen to twenty-eight hours after the last paroxysm. Also, this drug appears to be effective only in inhibiting *P. vivax* and not *P. malariae* or *P. falciparum*. Kaplan, Read and Becker<sup>74</sup> have studied the action of thiobismol in therapeutic quartan malaria more recently. This study shows that the drug has a predictable action in reducing the frequency of paroxysms in double or quotidian quartan malaria if the parasitemia prior to injection is below 10,000 per cubic millimeter. Again the drug was not effective on young or mature parasites. The absence of laboratory control of infections in most hospitals and the unpredictable interruptions of paroxysms when injections are not properly timed with the parasite cycle make the use of thiobismol against quartan infections impracticable.

### CHEMOTHERAPY

Advances in the chemotherapy of malaria are almost entirely the result of an extensive wartime research program. The program was dictated by the necessity of fighting in malarious areas and by the urgent need of prophylactic and curative drugs that would offset the grave loss of the source of quinine from the Netherlands East Indies. Although the losses from World War II are beyond calculation, mankind will benefit for years to come by the vision, skill and co-operation of American and British workers, who demonstrated how to use quinacrine most effectively, who synthesized and tested thousands of drugs and who proved the value of new antimalarial drugs.

Therapeutic problems with malaria involve the need of a drug to act as a prophylactic preventive of infection by killing the infective stages, or sporozoites, injected when the mosquito bites or by preventing the parasites from entering and from developing in the blood stream to cause the disease. In benign tertian malaria, a drug to be of specific value must produce not only a clinical cure but also a radical cure by destroying the hypothetical tissue stages of parasites that are responsible for relapses. The same requirement applies to drugs needed to produce a radical cure with latent malaria (*P. malariae*).

As previously stated<sup>1</sup> there was no agreement among clinicians in malarious areas about the dosage of quinine and quinacrine to be used in the treatment of malaria and about the results. It should also be pointed out that the dosages then in use for man were largely arrived at on empirical grounds. Little was known about their fundamental pharmacology, range of tolerance, most effective dosage schedules, mode of action on parasites and strain susceptibility to the two drugs.

### Quinacrine

At the beginning of World War II, quinacrine was the most effective antimalarial drug available.

The drug had an unfortunate reputation for toxicity, and no large quantities were being produced. Fortunately, the results of a concentrated pharmacologic and clinical testing program, combined with pharmaceutical skill, which enabled the manufacture of great quantities of this drug, made the difference between success and failure of military operations in tropical and subtropical theaters of war. New drugs were produced before the end of the war, but screening for antimalarial properties by animal injections, clinical testing, field trials and manufacture consumed too much time to make them a factor in field operations. Perhaps they can now be considered weapons to benefit the public health in peace.

The extensive synthesis of new compounds and the pharmacologic and clinical testing program in this country have been documented.<sup>75</sup> The broad organization that guided the emphasis and reasoning of the research projects will not be discussed here. The contributions, the majority of which are still unpublished, are so numerous that they can be discussed only briefly. To the discussion will be added the antimalarial studies and discoveries of British investigators that are of interest and practical application to clinicians.

Extensive pharmacologic, clinical, laboratory and field studies have made quinacrine one of the better known drugs. The pharmacologic behavior, advantages and disadvantages of this antimalarial agent are now known. The studies of Shannon and his collaborators<sup>76-78</sup> showed that the efficacy of quinacrine as a suppressive and as a clinical cure for malaria depended upon the plasma concentration of the drug. Analyses of blood concentration in man after the previously recommended dosage schedules revealed the difficulty and inadequacy of obtaining effective blood levels quickly. However, when a priming or loading dose of the drug was given on the first day, high plasma concentrations were obtained more quickly. The dosage is then lowered on the second day, and the required level can easily be maintained to complete the course.

Thus, the recommended therapeutic dosage of quinacrine for clinical malaria in adults is now two tablets of 0.1 gm (a total of 3 gr) and 1 gm (15 gr) of sodium bicarbonate by mouth every six hours for five doses and then one tablet of 0.1 gm three times daily for six days (total dosage, 2.8 gm in seven days).<sup>79</sup> Each dose should be taken with a full glass of water, sweetened tea or fruit juice after a meal to avoid gastric discomfort.

The principles involved with the correlation of plasma concentration for suppressive or therapeutic effects have been questioned.<sup>80</sup> Available data show that on the basis of plasma concentration quinacrine is over a hundred times more active than quinine. On the basis of oral dosage quinacrine is only three times more active. Thus, dosage schedules appear, in the words of Marshall,<sup>81</sup>

When great numbers of relapsing vivax malarial infections developed during the Pacific war, the extent and seriousness of the problem led to a reconsideration of the properties of existing antimalarial drugs. The revised dosage schedule with quinacrine provided radical cures with falciparum malaria, but the relapse rate with vivax malaria was not affected. Thus, plasmochin combined with quinine was the only known therapy that lowered relapse rates of vivax malaria. The high toxicity of plasmochin prevented its general use, but Most et al.<sup>104</sup> and Warthin and his co-workers<sup>105</sup> have used the combined plasmochin-quinine therapy to reduce relapses in vivax malaria. Nevertheless, less toxic analogues were sought. That search has now resulted in the discovery of two new and less toxic 8-aminoquinoline compounds<sup>106,107</sup> called pentaquine (SN-13,276) and SN-13,274. The latter drug has not been named officially, but the name isopentaquine has been suggested.<sup>107</sup> These drugs when used singly in combined therapy with quinine are said to reduce the relapse rate of vivax malaria by 85 per cent. The compounds are not commercially available at the time of writing, but they should become available in the near future.

The recommended dosage applies only to clinical and radical cures of vivax malaria with pentaquine and quinine. The drugs are too toxic for suppressive or prophylactic use. "A daily dose of 60 mg base (equivalent to 80 mg of diphosphate) and 2 gm of quinine administered concurrently" in divided doses every four hours for fourteen days is sufficient to produce radical cure of severe infections due to *P. vivax*. The drug is to be given only under close medical supervision and in a hospital if possible.<sup>106</sup>

Thus, we now have new drugs for the prophylaxis, suppression and treatment of malaria. Each drug appears to have special attributes against certain species and stages of plasmodia, but no drug answers the ideal requirements. The evidence is not sufficient to offer a final evaluation of any one of the new drugs. Furthermore, the claims made by some clinicians or malarialogists will probably be discredited later by others. When those who test new drugs realize that malaria occurs in many races of people having different body weights, habits and diets, and natural or acquired immunity, the results of clinical trials can be compared more readily. The conditions of trial in various parts of the world are also dissimilar. Thus, to avoid controversy when results are compared, the many and varying factors of the drug tests should provide the foundation for interpretation.

The effective dosage of chloroquine (aralen) for suppression of malaria is 0.3 gm of the base, but the manufacturers produce the drug as a diphosphate in tablets of 0.25 gm, and hence 0.5 gm (two tablets of 0.25 gm) in a single dose once in a week is recommended<sup>88, 89</sup>. In clinical malaria, an initial dose of 1 gm followed by an additional 0.5 gm in six to eight hours and then a single dose of 0.5 gm on each of two consecutive days is recommended<sup>88, 89</sup>. (The total dosage of 2.5 gm, or ten tablets of 0.25 gm each, in three days is higher than that used by Most et al<sup>90</sup>—1.5 gm—for acute vivax malaria, but the higher dosage is calculated to make allowance for the salt content of the commercial preparation.)

### Paludrine

An entirely different type of antimalarial drug was discovered during the war by British investigators and announced in 1945<sup>91, 92</sup>. This drug, originally called paludrine (synonyms-M-4888, SN-12,837 and chlorguanide hydrochloride),<sup>75, 93, 94</sup> represents another milestone in the efforts of man to find an ideal drug for true causal prophylaxis and treatment of malaria.

A series of researches<sup>93</sup> was initiated in an effort to explore compounds with different ring structures that would give antimalarial activity against the tissue stages of the parasites. The pyrimidine compounds were selected because of the need for this ring structure as a building block for nucleoproteins and because of the importance of nuclear components for cell growth and multiplication. The chance that analogues of essential pyrimidines might interfere with growth in the way that sulfonamides interfere with utilization of para-aminobenzoic acid seemed worth investigation.

Anilino-pyrimidines were prepared and tested and the compound "2666" was found to have antimalarial activity against *P. gallinaceum* in chicks. After the synthesis and testing of many more compounds, it was found that compounds containing a guanidine group and without the pyrimidine ring exhibited outstanding antimalarial properties. Thus, the new drug N<sub>1</sub>-p-chlorophenyl-N<sub>1</sub>-isopropylbiguanide acetate, called paludrine, was developed<sup>95</sup>. The salt of this drug now in use is the hydrochloride.

This drug was screened against four species of avian plasmodia and then tested in England<sup>96, 97</sup> and Australia<sup>98, 99</sup> against types of malaria in human beings. The clinical testing in Australia involved 200 volunteers infected with the highly virulent New Guinea strains of parasites. The results of clinical trials in this country have not been published, but reports of more recent field trials are beginning to appear. The results of comparative trials with chloroquine and paludrine under identical conditions and in a variety of patients of different age groups will be awaited with interest.

The prime advantage of paludrine over other antimalarial drugs is that it is a true causal prophylactic for falciparum malaria, giving complete protection against this parasite when the proper dosage is taken. The drug will also give radical cures of this lethal type of malaria. Although the drug will suppress and give clinical cures of vivax malaria, relapses will occur. The drug acts against the hypothetical tissue stages of falciparum malaria and against the asexual stages of *P. falciparum* and *P. vivax* in blood that are responsible for the clinical symptoms. The action against the circulating stages consists of prevention of multiplication and sterilization of gametocytes so that they cannot develop into infective stages in the anopheline mosquito. The rapid excretion of the drug within forty-eight hours<sup>100, 101</sup> and its failure to stop gametocyte production in falciparum malaria<sup>94, 102</sup> are disturbing findings that need more complete investigation.

The toxic dose is approximately two hundred times the therapeutic dose, so that the drug is relatively harmless. Dosages over 1 gm daily may give rise to gastrointestinal disturbances such as vomiting, abdominal pain, diarrhea and urinary symptoms including hematuria, sheets of epithelial cells and hyaline or granular casts. The symptoms subside when the drug is discontinued<sup>94, 99</sup>.

The dosage for causal prophylaxis of *P. falciparum* infection is 0.1 gm twice weekly. A single dose of 0.3 gm once weekly is usually effective in suppressing clinical symptoms and parasitemia of both malignant and benign tertian malarias. In a radical cure of falciparum malaria, 0.3 gm once daily for ten days is usually effective. For vivax malaria, the same dosage may be employed, but no radical cure can be obtained and clinical improvement is very much slower than that after administration of quinacrine or chloroquine. Viswanathan and Bailey<sup>102</sup> treated 8 patients with quartan malaria and found that the temperature persisted from two to five days after the first dose of the drug, which was in contrast to the short duration of temperature and parasite prevalence in falciparum malaria. More field trials are needed before the efficacy against quartan malaria can be assessed.

### Pentaquine

Before World War II, the only drug that was effective against the gametocytes of *P. falciparum* was plasmochin (synonym, pamaquine). The relatively low relapse rate with vivax malaria after combined therapy with plasmochin and quinine had been noted by a number of investigators in India and Panama<sup>103</sup>. Although plasmochin was included in the initial recommended therapy for malaria by the Army, high toxicity and little need for gametocidal properties caused its use to be discontinued.

suggests that she could have been pregnant. She then had a heavy flow. How long that lasted, whether she assumed that that was a menstrual period, or whether it was accompanied by pain, we do not know. Presumably it means that she had a very diffuse period and then had re-establishment of the menses, because nothing is said about further irregularity of bleeding until finally she is said to have missed the last period. In other words, two weeks before admission she was due to have a period but did not have one. What could have become of this pregnancy, if she were pregnant? It seems unlikely that she could have had an abortion of a living two months' fetus during the "heavy flow," because that would have impressed her sufficiently for her to have reported it as a miscarriage. She could, however, have had a blighted ovum and completely aborted it during the period of "diffuse flowing." It seems rather unlikely that she could have had a so-called missed abortion — that is, a blighted ovum that remained in the uterus, otherwise we would not expect her to have had re-establishment of periods, which we are assuming although it is not so stated.

She could also have had a tubal pregnancy six months earlier, which ended with the death of the fetus. That might well be followed by a profuse flowing and then by re-establishment of the menses. One can hardly believe that she terminated a tubal pregnancy with tubal abortion or tubal rupture because there is no history of pain or shock or anything of that sort. I think we can be quite sure that, whatever sort of pregnancy she may have had then, the fetus did not go on growing. As for the recently missed period, she was about two weeks overdue, and we will leave the possible significance of that until later. I notice that no information about the size of the uterus is given. Is there anything in the record about its size? Presumably it was not particularly enlarged or, I suppose, it would have been mentioned.

DR DANIEL S. ELLIS: Dr Meigs did a pelvic examination after the fluid had been withdrawn, but he did not think the uterus was abnormally large, this mass in the left vault was something very vague.

DR SMITH: I do not believe that the laboratory work has much bearing on the diagnosis. I see, however, that there is no report on the urine examination, presumably, it was negative since nothing is said about it.

The essential points about this patient are that she developed ascites with bloody fluid, possibly a pelvic mass, occurring in a woman who was previously healthy without any history of cardiac, renal or liver disease. To my mind, that is strongly suggestive of a malignant tumor in the abdomen. However, she had missed a period recently and she had a positive test for pregnancy. Furthermore, she had not only bloody fluid in the ab-

domen but also a great deal of bleeding, and I presume that we have to stop and consider whether the recent pregnancy was concerned in this condition at all. I do not recall ever hearing of ascites developing in a normal intrauterine or any sort of extrauterine pregnancy. It is worth noting perhaps that the ascites began almost as soon as this hypothetical recent pregnancy, because she noticed swelling of the abdomen ten days before admission, and presumably the ascites had begun some few days before she had noticed it. The period was due two weeks before admission, but at the time she noticed the abdominal swelling she was only four days over the period and that puts the onset of ascites back to a time when she could not have been more than ten to fourteen days' pregnant. I do not believe that we need dwell on a possible pregnancy having anything to do with the ascites.

It is quite possible, of course, that she had a coincidental pregnancy. Suppose that she had a malignant abdominal tumor, with bloody ascites, and just happened to become pregnant at that time. In that case the pregnancy would not be of any particular importance at the moment. However, there are one or two suspicious things about the case. One of them, of course, is that an obstetrician has been invited to discuss it, and it is hard to escape the feeling that we have to tie this up with pregnancy somehow. But there is another, more objective suspicion, and that is the extent of the bleeding. The woman had not only bloody fluid but also a fairly profuse intraperitoneal hemorrhage. According to the count, I should think there was a good deal more blood in the fluid than one ordinarily gets with a malignant lesion of the abdomen, such as a cancer of the ovary. This bleeding, of course, occurred after admission to the hospital — at least, the greater part of it did, because on admission she had a large, distended abdomen, but she had a normal blood pressure and pulse and the hemoglobin was 12.2 gm, which is not far below normal. What possible connection could a recent pregnancy have with this? Could a pregnancy in any way have contributed to this bleeding? Could she perhaps have had a pelvic tumor with ascites, either benign or malignant, and could the bleeding have occurred into this ascitic fluid from the pregnancy, whatever the pregnancy may have been? In that event, of course, there would have been the disadvantage of having to make two entirely separate diagnoses, which is somewhat hazardous as a rule. Furthermore, the only way that this amount of blood in the abdomen could have resulted from a pregnancy would be rupture of the uterus or an ectopic pregnancy. In the first place, the pregnancy as I pointed out earlier, was at the most four weeks along. Spontaneous rupture of a uterus with a normal intrauterine pregnancy is exceedingly rare as early as that. It does occur, but usually in the third or

BENJAMIN CASTLEMAN, MD, *Associate Editor*

EDITH E PARRIS, *Assistant Editor*

### CASE 34281

#### PRESENTATION OF CASE

A twenty-seven-year-old housewife entered the hospital because of abdominal swelling.

The patient had felt well until ten days before admission, when she began to notice abdominal swelling and nausea. Five days before admission she had pronounced abdominal fullness with vomiting, belching and passage of flatus. She was unable to take solid food.

She had been married five years and had two children. In the past three years she was unable to become pregnant. Her menstrual periods were regular until six months previously, when she skipped two menses and then had a heavy flow, and two weeks previously, when she missed her expected period.

There was no history of fever, jaundice or edema of the ankles.

Physical examination disclosed a well developed woman in no distress. The chest was clear. There was slight elevation of the right leaf of the diaphragm. The abdomen was enlarged, and there were generalized tenderness and shifting dullness. Pelvic examination revealed a soft, poorly defined, rounded mass in the left fornix. The uterus was freely movable, and there was no tenderness.

The temperature, pulse and respirations were normal. The blood pressure was 115 systolic, 70 diastolic.

Examination of the blood revealed the patient to be Rh+. The hemoglobin was 12.2 gm, and the white-cell count was 8900, with 71 per cent neutrophils. The total serum protein was 4.91 gm per 100 cc, with an albumin-globulin ratio of 1.90. The prothrombin time was 26 seconds (control, 17 seconds). The chloride was 99 milliequiv per liter, and the nonprotein nitrogen 18 mg per 100 cc. A van den Bergh reaction was normal, a cephalin flocculation test was ++ in forty-eight hours, and the bromsulfalein test showed 4 per cent retention of the dye. A blood Hinton test was negative. The stool gave a negative guaiac test.

X-ray examination revealed at least two rounded shadows of increased density in the right lung and another in the left and a small amount of fluid in the right pleural cavity. In the abdomen there was an area of hazy density apparently due to fluid, and a shadow suggesting the possibility of a mass in the pelvis. A gastrointestinal series was negative.

By the third hospital day the abdominal girth had increased from 91 to 96 cm, and there was a greenish discoloration in the umbilicus. An abdominal paracentesis yielded 4 liters of bloody fluid, with a specific gravity of 1.024, and a total protein of 3.73 gm per 100 cc. Cytologic examination disclosed 777,200 red cells, 560 polymorphonuclear leukocytes and 20 lymphocytes per cubic millimeter. By the fifth hospital day the hemoglobin was reduced to 7.5 gm, with a red-cell count of 2,480,000, and later to 6.6 gm, with a red-cell count of 2,200,000 and a white-cell count of 4500. A mouse test of the urine for pregnancy was positive. By this time the patient was beginning to have a low-grade fever. She was given two successive transfusions, and an operation was performed on the twelfth hospital day.

#### DIFFERENTIAL DIAGNOSIS

DR JUDSON A SMITH. Let us pause to analyze the menstrual history. Although it is inadequate we can perhaps make certain deductions from it. In the first place, the fact that the patient had missed two periods six months previously

of the pregnancy. The specimen of the fluid was sent to the cytologic laboratory, and at the time of operation we had a telephone report that no malignant cells had been seen in it.

#### CLINICAL DIAGNOSIS

Ovarian tumor

DR SMITH'S DIAGNOSIS

Chorioepithelioma, extrauterine, with pulmonary metastases

#### ANATOMICAL DIAGNOSES

*Papillary serous adenocarcinoma*

Uterine pregnancy

#### PATHOLOGICAL DISCUSSION

DR TRACY B MALLORY: Dr Meigs, will you tell us what you found at operation?

DR JOE V MEIGS: There were 3 or 4 liters of bloody fluid in the abdomen. The uterus was enlarged and was consistent with an early pregnancy. In the left ovary was an encapsulated, solid tumor, 20 cm in diameter, which on opening was filled with dark reddish, necrotic material. The other ovary was slightly cystic. There was no evidence of metastases anywhere within the abdomen, the lymph nodes were not enlarged, and there were no papillary projections on the peritoneum. A total hysterectomy and bilateral salpingo-oophorectomy were done.

DR MALLORY: The tumor was a solid ovarian carcinoma, with very extensive hemorrhagic necrosis of a large portion of the tumor. The cells microscopically were very anaplastic, but showed a tendency to papillary formation. The uterus disclosed a perfectly normal pregnancy in one corner, with a fetus 15 cm in length.

The patient returned to the hospital four months after discharge because of epileptiform seizures which were undoubtedly due to cerebral metastases, and died at home a few months later.

#### CASE 34282

##### PRESENTATION OF CASE

A twenty-two-year-old unmarried graduate nurse was admitted to the hospital.

She had been well until nine months before entry, at which time she had an attack of fever and abdominal pain associated with prolongation of menstrual periods. At that time she was studied at

another hospital, and some suspicion of paratyphoid infection was entertained but never proved. A low-grade fever persisted for several weeks and then spontaneously disappeared. Eight months before entry she had, for the first time, considerable pain with the catamenia and more profuse flowing both in amount and in duration than she had previously had. Subsequent to this, the periods were irregular, occurring every thirty-four to forty days rather than every twenty-nine days as previously. With each period she had severe lower abdominal cramps and backache. Between the periods she felt reasonably well and was able to continue her work. Five days before admission to the hospital she was examined. At that time it was found that the last menstrual period had begun nine days previously and had been extremely painful, with profuse flow, lasting for seven days. Associated with the period was a temperature as high as 101°F. The patient was unable to work and was so uncomfortable that she had to go to bed. At the time of examination the pain in the abdomen was still present although she had had no menstrual flowing for two days. Physical examination at that time showed diffuse tenderness throughout the lower abdomen, most marked in the right lower quadrant and associated with a moderate degree of resistance in the latter location. On bimanual pelvic examination the pelvic organs were not made out. There was some tenderness in the right vault, no mass was felt. The cervix was normal to inspection and to palpation. On the anterior vaginal wall there was a very tiny nodule, which seemed to be compatible with an endometrial implant. There was some tenderness also in the left vault, but not enough to interfere with the examination, and no masses were felt. Rectal examination gave no additional information. Because of persistence of the symptoms she was admitted to the hospital.

Except for an appendectomy five years before entry, the past history was irrelevant.

On physical examination no additional information was obtained.

The temperature, pulse and respirations were normal. The blood pressure was 130 systolic, 70 diastolic.

The urine was normal. The white-cell count was 10,700, with 53 per cent neutrophils, 1 per cent large lymphocytes, 36 per cent small lymphocytes, 8 per cent monocytes and 2 per cent eosinophils.

fourth month. If the uterus was ruptured, one would have expected some external bleeding. Also, against either a ruptured uterus or ectopic pregnancy is the fact that the bleeding, although profuse, had apparently not been sudden. It occurred over a few days, and it did not produce pain or any symptoms of collapse, which we associate with rupture of a tubal pregnancy or rupture of a uterus. On the whole, I think we can dismiss the idea of a ruptured uterus in any sort of pregnancy.

On the other hand, one cannot get away from the fact that there was very profuse bleeding, as well as a positive Aschheim-Zondek test, and one wonders if the whole thing can be accounted for by a particular type of tumor. A chorioepithelioma will produce all these signs. It is a very rapidly growing tumor and is notorious for invading blood vessels. It could easily produce this amount of bleeding, as well as the mass in the pelvis, and could account for the positive Aschheim-Zondek test. I believe that a malignant tumor, a chorioepithelioma, is the most probable diagnosis. The possible pregnancy six months before admission is an obvious source. Whether it was a blighted ovum or a complete abortion or a pregnancy, a chorioepithelioma could still have developed in the tube or in the uterus. The fact that six months elapsed is not against that diagnosis because it is well known that there may be a long latent period between pregnancy and the development of this tumor. It is also possible, of course, for a chorioepithelioma to develop coincidentally with pregnancy, although I think it is rather unlikely that a chorioepithelioma could have developed during the past month at the onset of this hypothetical recent pregnancy. And, of course, when one gets right down to it the patient was not necessarily pregnant at all because she could have had a teratoma with chorioepitheliomatous elements in it. That is a rather farfetched diagnosis, but it has happened.

There are a number of things that would help us to confirm this diagnosis. Chorioepithelioma is well known to metastasize early and very frequently to the lung. If these pulmonary shadows on the x-ray film are consistent with metastatic tumor, I should think it would go a long way toward confirming that diagnosis. Another procedure, which was not recorded but which I am

sure must have been done, is examination of the fluid for malignant cells. Then there is the question of the quantitative Aschheim-Zondek test. Perhaps that was performed. This tumor frequently metastasizes to the vagina as bluish nodules that are quite diagnostic. I do not suppose that if such nodules had been noticed they would have been included in the record—that would have made the diagnosis too easy. I think that the most important clue we can ask for is from the X-ray Department. If the presence of tumor is not confirmed, I still think that she probably had a malignant tumor, most likely a chorioepithelioma. I do not believe that one can decide where it originated, on the information we have, but one can draw certain deductions. It is quite unlikely, of course, that it was growing inside the uterus because there had been no recent uterine bleeding. It could have been an intramural nodule. In that case, the abdominal symptoms were probably due to the growth of a metastasis because had the tumor grown rapidly through the uterine wall to involve the adjacent structures, I would expect the tumor not to be freely movable and so easily felt. My guess would be, if she had a chorioepithelioma, that it probably originated outside the uterus.

DR STANLEY M. WYMAN: The masses described in the right lung are in the midlung field, the third nodule lies in the left lower-lung field. Examination about three weeks later showed the three nodules to have increased definitely in size. They have an appearance that is quite characteristic of metastatic disease. The film of the abdomen shows nothing more than probable fluid. I cannot make out a definite mass and I can see no evidence of unusual calcification.

DR ELLIS: This patient was admitted to the hospital with a diagnosis of cirrhosis of the liver, primarily because of the ascites and the fact that nausea and vomiting played a predominant role in the symptoms in the ten days prior to admission. When she came in, it was obvious when one saw her and went into the history carefully and from the various laboratory studies that she did not have cirrhosis. Regarding Dr. Smith's questions about the period that she had six months prior to admission, the patient herself described it as a miscarriage although careful questioning did not reveal that she had actually identified the products

spasm and tenderness in the right lower quadrant, and this suggests a dermoid rather than a follicular cyst. I shall make a diagnosis of twisted dermoid cyst of the right ovary

DR BENJAMIN CASTLEMAN The preoperative diagnosis that Dr Leland S McKittrick made was "pelvic pain, cause undetermined" Can you tell us about the operation, Dr McKittrick?

DR JOHN B MCKITTRICK This patient was seen by several doctors, who were unable to make a more accurate diagnosis The question of pregnancy or pelvic inflammatory disease was raised, but there was no reasonable evidence for such a diagnosis She had no vaginal discharge The cervix was perfectly normal, there was no suggestion of pelvic inflammatory disease either clinically or by physical examination Physical examination was difficult because of the mechanical situation She was very large, with an extremely difficult pelvis to examine purely because of the size Even under ether it was not easy to determine what was in the pelvis We approached the situation with no diagnosis except excruciating pelvic pain

#### CLINICAL DIAGNOSIS

Pelvic pain, cause undetermined

#### DR ULFELDER'S DIAGNOSIS

Twisted dermoid cyst of ovary

#### ANATOMICAL DIAGNOSIS

*Tuberculous salpingitis and endometritis*

#### PATHOLOGICAL DISCUSSION

DR MCKITTRICK At the time of operation we were surprised to find that both tubes were involved in the process The left was worse than the right It was swollen, and the fimbriated end obliterated The tube was nodular throughout The right tube was obstructed just proximal to the fimbriated end and was nodular but less swollen and thickened than the left tube Over the anterior surface of the uterus were multiple, white, miliary nodules Our gross diagnosis at operation was tuberculosis A curettage had been performed preliminary to laparotomy, but very little tissue was obtained and nothing characteristic was determined on appearance The diagnosis of tuberculosis was subsequently confirmed grossly by Dr

Castleman, who saw the patient in the operating room

We removed a portion of the left tube for a biopsy Elsewhere in the peritoneal cavity there was no evidence of disease After much discussion it was decided not to do anything more surgically and to send the patient to a sanatorium

DR CASTLEMAN Our permanent microscopical sections showed an active tuberculous process not only in the tube but also in the endometrium

DR MCKITTRICK Within two months after arrival at the sanatorium, the symptoms became so severe and persistent that it was thought advisable to do a hysterectomy At the time of the second operation the disease had spread although the ovaries were not involved A supravaginal hysterectomy was done The patient remained well for about two months after the laparotomy and then had a recurrence of severe excruciating pain, with profuse discharge from the vagina, and later developed urinary symptoms I think it was established that the vaginal discharge was caused by tuberculosis, but the urinary-tract disease was never, to my knowledge, proved to be tuberculosis She was treated with streptomycin for three months, but it was stopped when she developed severe vertigo I have not heard from her recently, but ten months after the operation she was still having a difficult time, still having pain and profuse discharge For a while the streptomycin slowed up the discharge I do not know what the course was from that time on Dr King saw the patient It would be interesting to hear what he has to say

DR DONALD S KING I saw her after her first operation and found no active pulmonary tuberculosis

DR MCKITTRICK We looked hard for generalized tuberculosis but found none whatsoever

DR CASTLEMAN Do you think that the entire uterus should have been taken out?

DR ULFELDER In retrospect, there is no question that she had tuberculosis of the cervix which accounted for the continued vaginal discharge

A PHYSICIAN I saw this patient two days ago, which is just about two years since she was in this hospital She now has a vesicovaginal fistula, and they are finding tubercle bacilli in the urine on each examination There is some discussion now about taking out the kidney It is a rather stormy outlook

The red cells and platelets appeared normal. The photohemoglobin was 15.1 gm. The sedimentation rate was 0 mm in 15 minutes, 1 mm in 30 minutes, 1 mm in 45 minutes, and 2 mm in 60 minutes.

On the third hospital day a laparotomy was performed because of the persistence of abdominal pain.

#### DIFFERENTIAL DIAGNOSIS

DR HOWARD ULFELDER: This is the history of a young unmarried woman who had two attacks of abdominal pain and fever coincident with the menses. The first attack was nine months prior to admission and the second, two weeks before admission. In the interval between attacks she was well enough to work but noticed a change in the menstrual cycle, the interval increased somewhat, and she developed severe cramps, which apparently she had not had before the present illness. The fever and abdominal pain suggest to me that we are presented with either an inflammatory lesion or ischemia, although one occasionally sees tumors with fever. The location of this lesion was apparently the right lower quadrant, probably in the true pelvis because of spasm and tenderness of the right lower quadrant and some tenderness, which prevented an adequate pelvic examination. I wonder if it was unilateral in the pelvis? Certainly the majority of physical findings were on the right side, but we are told that she had some tenderness on the left side also. Is there anything that can help us localize this lesion more precisely? Were any x-ray films taken? Did she have pyelograms or a barium enema?

DR JOHN B. MCKITTRICK: No.

DR ULFELDER: Apparently, the gastrointestinal and the urinary tracts were not believed to be involved. There was a normal sedimentation rate and hemoglobin and an essentially normal differential count, despite elevation of the white-cell count.

Does the past history help? An appendectomy had been performed five years previously. It is conceivable that something incident to the appendectomy produced the present picture. One thinks of a foreign body, either a fecalith or some other foreign body, left at the time of appendectomy, and producing abscess in the right pelvis. I consider these unlikely, however.

Is there anything in the history to suggest pelvic inflammatory disease? We have no history of vaginal discharge or exposure to gonorrhea.

Does the character of onset of this illness suggest a complication of pregnancy? We are not told whether the bleeding with the first attack was at the expected time of menstruation or whether there had been an abnormal interval between the last normal period and the period described as occurring at the time of the original attack of pain and fever. One must consider the possibility that this patient had a pregnancy with an early miscarriage, with the retention of some products of conception and recurrent infection in the endometrium. To try to interpret the menstrual history is almost futile. The menstrual history that this patient gave may be that of anyone, including a girl who has no organic lesion.

We have been presented with the statement that she had a tiny nodule in the anterior vaginal wall, which seemed to be compatible with an endometrial implant. Endometriosis of the vaginal wall is rare. Endometriosis as an explanation of this picture in a twenty-two-year-old woman is extremely rare. I do not consider endometriosis a very strong possibility in this patient.

To summarize, it is my opinion that this patient was suffering from a lesion in the right pelvis connected with the genital tract, which was either inflammatory or ischemic in character. Foreign body is a possibility, I do not consider it very seriously. Pelvic inflammatory disease is a strong possibility. I have mentioned the possibility of a retained placental fragment, that must be considered. Tuberculosis, lymphoma or congenital anomaly might explain the picture. The congenital anomaly that I have in mind, as a possible but not a likely explanation, is a double uterus with a very small uterus on the right side and a normal one on the left side, with some obstruction in the canal from the small right-sided uterus. I do not consider it seriously but merely mention it.

My belief is that this patient suffered from a lesion that was primarily ischemic and recurrent, and, therefore, I believe that a cyst of the right ovary with torsion is the most likely diagnosis. I had hoped an x-ray film might help in deciding whether or not a cyst was present, and if present, whether it contained calcification. The lesion seemed to be anterior, in that the patient had

personnel during the war and has also occurred not infrequently in civilian practice

Attention is now being focused on a new mode of transmission of this serious form of hepatitis — namely by means of the unsterile or inadequately sterilized needle or syringe. British workers have called attention to the frequent occurrence of such transmission during the treatment of syphilitic patients, in whom it is considered to be the chief cause of the so-called arsphenamine hepatitis<sup>1 2</sup>. It has also been implicated as a possible cause of an outbreak of hepatitis in a diabetic clinic<sup>3</sup> and as the cause of similar illnesses in patients who are under treatment with penicillin for a variety of diseases<sup>4-6</sup>. Furthermore infectious hepatitis can be transmitted from one patient to another by syringes used for the collection of blood<sup>7</sup> and this was probably the mode of transmission in the diabetic clinic.

The syringe transmission of hepatitis is made possible by the fact that very little blood or serum of an infected carrier is necessary to transmit the disease and also by the fact that the causative virus is a hardy one that resists the cursory types of sterilization that are often practiced in busy clinics in which numerous blood samples are drawn or many injections have to be given in a short time. Mendelssohn and Witts<sup>8</sup> showed that during an ordinary venipuncture some of the blood is sucked back from the syringe when the tourniquet is released and this permits infected materials previously present in the syringe or needle to enter the blood stream of the patient whose blood is being drawn. It has also been demonstrated that during the course of an injection some blood or serum from the patient may be forced up through the needle during the contraction of the recipient's muscle, thus resulting in contamination of the syringe.

Capps, Sborov and Scheiffel<sup>9</sup> have recently reported an epidemic of infectious hepatitis apparently resulting from the use of the "multiple dose per syringe" for the administration of tetanus toxoid. In this outbreak 20 per cent of the recipients of the toxoid contracted acute infectious hepatitis. It was estimated that about five per cent of the original group of people being vaccinated must have carried the hepatitis virus in their blood, and

it is believed that the syringes became contaminated with the blood from these persons before all the toxoid had been dispensed. Although separate needles were used for subsequent inoculations of the toxoid from these syringes a large proportion of those receiving the later injections were inoculated with the virus and thus later came down with the hepatitis.

The implications of these findings are obvious. Modern medical practice involves considerable use of needles and syringes for bloodletting and also for various types of injections. These facts and the tremendous development of the use of whole blood and blood products and the general system of blood banks being established in this country all point to the importance of this mode of transmitting such a serious disease. From the point of view of syringe transmission the significance of adequate sterilization is obvious. This can be accomplished by dry heat sterilization, autoclaving or boiling for about thirty minutes and the use of individual sterile needles and syringes for every puncture. The need for adequate supplies of needles and syringes in large clinics or when many injections must be given also becomes apparent.

## SMALLPOX TO TETANUS A HUNDRED AND FIFTY YEARS OF IMMUNIZATION

THE value of vaccination against smallpox cannot be questioned, but now, a century and a half after its effectiveness was clearly shown, vaccination is still by no means universally employed, even in certain enlightened areas in the United States. There are protests against its use from those who either cannot or will not see its merit. In earlier years the slowness of its adoption could be explained, in part, by the lack of efficient methods of demonstrating the good results to the public. Also, in the early stages of its use no really large-scale and well controlled figures were possible.

Today, with present methods of broadcasting knowledge, scientific and otherwise, no excuse can be offered for failure to recognize the benefits of immunization against tetanus. The not tabulated results of not thousands, but millions, of cases in the armed forces all over the world furnish conclusive evidence of the efficacy of immunization against tetanus. The procedure is simple, safe and relatively painless. The results admit of no argument regarding its effectiveness, as amply demonstrated by Press elsewhere in this issue of the *Journal*.

Scarcely a day goes by in which a physician does not see a case in which tetanus could result from a minor wound. In the days when tetanus antitoxin was his only recourse he was constantly obliged to make the important and sometimes difficult decision whether the patient should be subjected to such serum therapy, with its discomforts and its dangers, or whether by withholding it, to obviate these discomforts at the risk of the disease. Such a difficulty is no longer necessary.

There are, of course, those who protest against any and all progress in medicine. As there are conscientious objectors to vaccination against smallpox, so there are inevitably those who would object to any advance, even though the known facts of its efficacy permitted of no dispute.

It is most desirable, therefore, that general practitioners do what they can, and as much as they can, to promote the acceptance by the public of active immunization against tetanus. Tetanus toxoid will protect the individual person, and its universal use may greatly ease the burdens of the physician.

## SYRINGE-TRANSMITTED HEPATITIS

THE occurrence of a severe form of hepatitis often referred to as "homologous serum jaundice" following injections of normal or immune plasma, serum or whole blood or after inoculations of certain vaccines containing normal serum or plasma is now well recognized. This type of hepatitis was observed in widespread epidemics in military

These new proposals represent a considerable willingness to compromise since even his own party is not entirely in sympathy with them

The Government according to Mr Bevan's parliamentary secretary, now recognizes that a full-time salaried service is incompatible with free choice of physician by the patient more, it recognizes the importance of the principle of free choice of physician and therefore puts forward the compromise of payment partly by capitation fee and partly by salary Further, although the buying and selling of public practices will still be forbidden, every doctor will be free to practice where he wishes except in professionally overcrowded areas and will have the right to choose his partner or assistant

A few strands of democracy will remain in Britain's anchor line, although, as the *British Medical Journal*\* phrases it, "Mr Bevan's machinery may provide that justice will be done, but we doubt whether it will make it possible that justice 'may manifestly be seen to be done'

A plebiscite on the amendments proposed by the Government indicates that approximately 64 per cent of the British Medical Association members still disapprove of the Act, with 36 per cent approving Only 52 per cent, however, are against serving under the Act whether they like it or not, a majority so bare that further organized resistance seems impossible

There is no question that, with Britain's peculiar genius for compromise, the doctors of England will now unite in an organized effort to make the new system effective

Whooping cough	134	495	573

\*Four year median

†Six year median.

COMMENT

Diseases with incidence above the seven-year median were diphtheria, bacillary dysentery, measles, mumps and typhoid fever

Diseases with an incidence below the seven-year median were chicken pox German measles malaria, meningitis, all forms, lobar pneumonia, scarlet fever, undulant fever and whooping cough

Mumps had the highest incidence since 1915 There were more cases of typhoid fever in May than in the last six years Whooping cough and lobar pneumonia were at the lowest level since 1915

GEOGRAPHIC DISTRIBUTION OF CERTAIN DISEASES

Diphtheria was reported from Boston, 7 Brockton, 4, Chelsea, 1 Everett, 1 East Bridgewater, 1, Peabody, 1 Somerville, 1, Watertown, 2, total, 18

Dysentery, bacillary, was reported from Waltham, 1 Worcester, 7, total, 8

Encephalus infectious, was reported from Cambridge, 2, Fitchburg, 1, Lowell, 1, Waltham, 1, total, 5

Malaria was reported from Boston, 1 total, 1

Meningitis meningococcal, was reported from Boston, 2 Everett, 1, Lynn, 1 Medford, 1, Newton, 1, Quincy, 1, total, 7

Meningitis, Pfeiffer-bacillus, was reported from Acton, 1, Lowell, 1 New Bedford, 2 total, 4

Meningitis, pneumococcal, was reported from Brookline, 1, Tewksbury, 1, total, 2

Meningitis, streptococcal, was reported from Cambridge, 1, total, 1

Meningitis, other forms, was reported from Boston, 1 Reading, 1, total 2

Meningitis undetermined, was reported from Braintree, 1, Newton, 1 Worcester, 1 total, 3

Salmonellosis was reported from Beverly, 3, Boston, 1, Haverhill, 1, Otis, 1 total, 6

Septic sore throat was reported from Boston 7 Medford, 1, Milton 1, total, 9

Tetanus was reported from Worcester, 1 total, 1

Typhoid fever was reported from Boston, 3, New Bedford, 1, Westfield, 1, total, 5

Undulant fever was reported from Easton, 1, Hopkinton, 1, Newton, 1, Webster, 1, total, 4

referred to in these columns<sup>2</sup> And the decline in the number of deaths from certain leading causes should be balanced against the increase in other fatal diseases Thus, although the deaths from intracranial lesions of vascular origin and from nephritis decreased, respectively, from 129,144 and 88,078 in 1945 to 125,649 and 81,701 in 1946, the deaths from cancer increased from 177,464 in 1945 to 182,000 in 1946, and those from heart disease from 424,328 to 429,230 One class of preventable deaths (those due to accidents), which rose from 95,918 in 1945 to 98,033 in 1946, remains both a challenge and a disgrace to a nation in which a great part of private and public-health medical practice is devoted to the prolongation of life

Cancer and other malignant tumors continue to take a large toll, accounting for 13 per cent of the total number of deaths in 1946 Although he admits the uncomfortable implications of such a figure, Johnson<sup>3</sup> points out some hopeful trends The rate of deaths from cancer at all ages rose from 60 per 100,000 population in 1900 to 130 per 100,000 in 1940, but this depressing figure should be considered in the light of the 67 per cent increase in the age group over forty-five years, in which the greatest incidence of cancer occurs And although the number of deaths from cancer of the respiratory tract continues to rise each year, deaths due to malignant lesions of the skin, mouth, stomach and liver have steadily decreased in the last twelve years — Johnson suggests an interesting causal relation between the decline in the death rate from gastric cancer and the fact that the decrease began approximately twenty-five years after significant changes in the dietary habits of the American people had taken place

Despite the truly remarkable advances in the control of disease and the prolongation of life, science has not succeeded in making man immortal Johnson<sup>3</sup> questions whether it is desirable to concentrate on that goal alone He expresses what should be a major consideration in the relatively new field of geriatrics, "the enrichment of living rather than the mere prolongation of life" There is no indication for congratulations in the vital statistics referred to above the five leading causes of death, whether they are the causes at present

responsible or others that will take their place, will continue to exact their yearly toll, particularly among the elderly And medical science will continue its campaign not only, by control of the diseases that cause most deaths, to extend the span of life but also to eliminate the physiologic discomforts that plague old age — in short, to avoid a "second age of dependency"<sup>4</sup> and make of old age a period of dignity and mental and physical well-being

#### LION ROARS LESS LOUDLY

THE Comitia of the Royal College of Physicians, acting in a spirit of sweet reasonableness, has forwarded two resolutions to the minister of health, Aneurin Bevan, vociferous sponsor of the National Health Service Act of 1946 The first suggests that an act be brought in by the minister of health amending the National Health Service Act of 1946 by discarding full-time medical service by regulation The second recommends a bill to make regulations affecting the National Health Service subject to special parliamentary procedure rather than to ministerial dictation alone

Mr Bevan, departing from his accustomed role, has apparently listened to the voice of the British Medical Association as expressed in its plebiscite of January 31, in which it overwhelmingly rejected the National Health Service Act as it was originally written

He has now proposed his own modifications of the Act In these he relinquishes a full-time service to be brought into effect by regulation and also modifies the proposal for a universal basic salary, limiting such salaries to three years, after which the practitioner may make his own decision whether to continue with salary and capitation fee, or to continue with a capitation fee as the sole source of income from practice

## NOTICES

## AMERICAN OCCUPATIONAL THERAPY ASSOCIATION

The thirty-first annual convention of the American Occupational Therapy Association will be held at the Hotel Pennsylvania, New York City, September 7 to 11. On September 10 and 11, a teaching institute will present recent developments and techniques in the treatment of neuropsychiatric conditions. Various trips to hospitals and other institutions in New York City and surrounding areas, on September 9 and 10, have also been arranged for those attending the convention. A copy of the preliminary program may be obtained from the American Occupational Therapy Association, 33 West 42nd Street, New York 18, New York.

### COUNCY AND THE ASSOCIATION OF AMERICAN PHYSICIANS

To the Editor The editorial, "Four Hundred and Thirty Years Ago," in the May 20 issue of the *Journal*, which I read with interest, contains a minor error, perhaps of no importance to anybody, but I think you might like to know about it. That concerns the Association of American Physicians and Dr. Councilman. I am sure that Dr. Councilman had very little to do with the founding of the Association of American Physicians, although he was one of sixty-nine original members. The reason I say that is that Dr. Councilman then was only eight years out of medical school, was an associate in pathology at the Johns Hopkins Hospital with Dr. Welch, beginning at a time when the hospital had not been built.

The editorial also states that he was known as "Councey." I never heard this term used. He was affectionately spoken of by the younger men as "Counce" and was known as "Counce" to many of his colleagues. Dr. Welch, of course, was always known to the younger men as "Popsy," though I never heard anyone call him that. He was always known as Dr. Welch, Welch, to a very few as William and to an occasional member of his family as Willie. I never knew who designated him first as Popsy. When I went to Johns Hopkins in the autumn of 1896 he was universally spoken of by the students as Popsy.

HENRY A. CHRISTIAN

#### Brookline

Note Dr. Councilman was later known to his students at Harvard Medical School as "Councey." — Ed

## BOOK REVIEW

*Surgical Treatment of the Abdomen*. Supervising editor Frederic W. Bancroft, M.D. Associate editor Preston A. Wade, M.D. 4<sup>th</sup> ed., cloth, 1026 pp. with 457 illustrations and 3 color plates. Philadelphia: J. B. Lippincott Company, 1947. \$18.00.

This comprehensive and authoritative volume was written by thirty-five eminent physicians. The scope of the book is sufficiently broad to comprise a thorough consideration of fundamental surgical principles applicable to the exacting requirements of gastrointestinal surgery. Adequate coverage is given to the common problems of anesthesia, preoperative and postoperative care and the essential features of a sound surgical technique. The sections relating to the various diseases involving the gastrointestinal tract are well documented and generously illustrated.

The chapter pertaining to the surgical lesions of the small bowel is particularly noteworthy in terms of its broad scope, its ample pictorial documentation and its careful presentation of the controversial aspects of the surgical management of lesions of the small intestine.

Each section, big and large, achieves the purpose of portraying the dominant clinical features of the diseases that are discussed—the diagnosis, an acceptable method of surgical management and a reasonable consideration of the results that can be achieved by the proposed methods of therapy.

Although one might question the urgent need for such a volume, no one could question its authoritativeness or its essential soundness.

## BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

*Atlas of Practical Incisions and Some Operative Procedures*. By Oliver C. Cox, M.D. 4<sup>th</sup> ed., cloth, 85 pp., with 27 illustrations and 61 plates. With drawings by Garnet W. Jex, and photographs by John W. McGuire. Baltimore: Williams and Wilkins Company, 1947. \$3.00.

In this atlas the author presents incisions recommended for various surgical operations on the gall bladder, appendix,

undescended testicle, hernia and pilonidal cyst, and considers the "reverse" Pfannenstiel and the Parker-Kerr aseptic enterocentrostomy. The plates are excellent and self-explanatory. There are short comments with each series of incisions, but otherwise there is no text. The volume is well published and should prove useful to students and beginners in surgery.

*George Crile. An autobiography*. Edited with sidelights, by Grace Crile. In two volumes. 8<sup>vo</sup>, cloth, Vol. I, 306 pp., Vol. II, 317 pp., illustrated. Philadelphia: J. B. Lippincott Company, 1947. \$10.00.

The material for this autobiography of a celebrated physician-scientist was compiled from the notes, letters, diaries and manuscripts of Dr. Crile, who also wrote the material for the early chapters, until his vision became impaired. Here will be found the history of his work on surgical shock, fear, blood pressure, surgery of the respiratory system, hemorrhage and transfusion, the thyroid gland, anemia and resuscitation, phylogenetic association, anoci-association, the emotions, kinetic drive and the bipolar theory. Dr. Crile made a life-long study of surgical shock and perfected a shockless operating technique. He performed the first successful amputation under local anesthesia in 1897 and the first successful blood transfusion in 1906. He perfected the nitrous oxide method of general anesthesia. He was a motivating force in the founding of the American College of Surgeons and the American Society of Clinical Research. Prior to World War I he set up an ambulance service in Paris and organized Red Cross Base Hospital Units. Later he was a member of the first contingent of the United States Army to serve overseas in the war, establishing a hospital at Rouen in 1917 before the arrival of troops. At the end of the war he was director of medical research for the Army. Returning to Cleveland he was instrumental in building and operating the Lakeside Clinic, which pioneered in radiotherapy and biophysics. Dr. Crile was a traveler. He made two European trips previous to his marriage and upon that occasion made a global trip. During the later years he made numerous trips to Europe, Africa, Alaska, California and Florida to study the endocrine functions of the larger animals and marine life. For this and other work he received many honors including the Lanne-longue surgical medal of the Surgical Society of Paris. This work should be in all medical-history collections.

*Hypnotherapy. A survey of the literature*. By Margaret Brennan, Ph.D., director, Division of Psychology, The Menninger Foundation, and professor of psychology, The Menninger Foundation Center of the Department of Psychology, University of Kansas, and Merton M. Gill, M.D., associate psychiatrist and assistant director, Department of Research, The Menninger Foundation. With appended case reports and an experimental study. 8<sup>vo</sup>, cloth, 276 pp. New York: International Universities Press, 1947. \$4.50. The Menninger Foundation Monograph Series No. 5.

This work was originally published by the Josiah Macy Jr. Foundation in 1944 and distributed to psychiatrists and psychologists as part of its wartime services. It is reissued in a commercial edition with two new appendices. The general bibliography lists 295 sources comprising the basis of the survey. The text is divided into six parts and two appendices. The first part is a short sketch on the historical development of hypnotherapy, followed by methods of inducing and terminating hypnosis, susceptibility of hypnosis, therapeutic applications, the theory of hypnosis, and a summary and statement of problems. The first appendix discusses in detail 4 unusual cases of anxiety hysteria, hysterical psychosis in a seventy-one-year-old woman, a case of combined neurasthenia, hysteria and depression, and a case of neurosis in a young girl, illustrating the techniques of hypnotherapy, hypnoanalysis and psychoanalysis. Seventy pages of text are devoted to these cases. The second appendix is devoted to a discussion of the use of hypnotic techniques in the study of tension systems, giving in detail accounts of the experiments used in the study. There are special bibliographies for the case reports and for the experimental study. The volume is well published, with a good type on good light paper. The work should be in all collections on psychiatry.

## EXCESSIVE HYPERTENSION OF LONG DURATION

ALEX M BURGESS, M D \*

PROVIDENCE, RHODE ISLAND

IN THE *Journal of the American Medical Association* of December 21, 1932, under the heading, "Queries and Minor Notes," appears the following question

Can you give me any statistics or other definite information of assistance in the prognosis of blood pressure? For example, how definitely can one say how long a person with a pressure of 200 systolic will survive, or one with 250, or one with a diastolic of 100 or 120? I realize that many factors enter in, but I am especially interested in the effect such high pressures have on individuals who show no cardiac or renal disease.

An answer to this question was prepared in the office of one of the largest insurance companies. Admittedly, it was incomplete and began, "There are no data available from insurance sources on the prognosis of individuals showing such high pressures, whether systolic or diastolic." Actually, the only available data that could give a real answer to the question are buried in the private records of practitioners who have followed hypertensive patients over long periods. If enough material could be obtained from such records by the collaboration of approximately a hundred physicians, real information would become available and the question could be given a definite answer.

The subject has great intrinsic importance, which has been considerably enhanced by public hypertensophobia. Such regrettable popular articles as that entitled "Killer Number One," which appeared in the *Saturday Evening Post* of December 16, 1944, have contributed to this state of affairs. Unfortunately, the medical profession has no reliable information on which to base reassurance of the unfortunate persons to whom the existence of high blood-pressure readings has been made known, and in whom a thoroughly reasonable anxiety state has been created.

When one encounters a young adult whose diastolic pressures range consistently over 120, whose eye grounds show extensive flame-shaped

hemorrhages, exudates or edema, and who already presents evidence of cardiac or renal damage, there is no difficulty in estimating the prognosis. Such frank cases of hypertension of the malignant type are readily recognized and the gravity of the situation is universally understood. When, however, one is confronted by a patient with excessive hypertension (even with systolic pressures from 200 to 300 and diastolic pressures over 120), and when there is evidence that the condition is not progressive, when retinal changes are minimal and cardiac and renal damage not evident, there is no reliable information on which to base a prognosis.

No previously reported studies have attempted, so far as has been determined, to separate the obviously nonprogressive type of hypertension from the obviously malignant type, and to study the prognosis in the nonmalignant group alone. Although fairly large series have been studied by Janeway in 1913,<sup>1</sup> Rice in 1933<sup>2</sup> and several others<sup>3-5</sup> there has been no unanimity in the method of approach, and the results are difficult to evaluate. A recent communication by King, Carlile and Blackford,<sup>6</sup> which includes a follow-up study of 481 patients, is perhaps the most valuable that has yet been published. In their tabulations "essential" and "malignant" hypertension have been classed together. Their results, therefore, do not indicate what may be expected in the nonmalignant, relatively nonprogressive condition.

Furthermore, the importance of the diastolic pressure has not been sufficiently stressed. Most investigators have, however, pointed out that the presence of a relatively high diastolic pressure is a definitely unfavorable sign although in their statistics they have evaluated the degree of hypertension in terms of systolic as well as diastolic levels and therefore have failed to demonstrate the significance of high diastolic values. The conclusion that a high diastolic pressure carries with it a definitely poor prognosis is, I believe, in accord with the experience of clinicians generally, based

Mead Johnson & Co , Evansville, Ind , U S.A

chances that any patient with excessive hypertension of long duration will live to his normal life expectancy are considered, the first factor of which one thinks is the age when the condition developed. In the patients reported it is notable that every person who was sixty-five years or over when excessive hypertension first was noted has outlived his life expectancy. The corollary to this statement, of course, is that persons in whom excessive hypertension was discovered relatively early in life and whose normal expectancy is therefore relatively long are unlikely to complete their life span. That this is true is demonstrated in Table 4, which shows what has happened to the 32 patients in whom the condition was discovered at the age of fifty

It is quite evident that an elevated systolic pressure is not, of itself, an unfavorable prognostic sign. In fact, the 27 patients who showed a systolic pressure of 250 or higher at some time while they were being observed lived distinctly nearer to their life expectancy than those in whom such high readings were never obtained. This is further emphasized by the fact that the 5 patients in whom a reading of over 300 was recorded on one or more occasions actually showed an average duration of life slightly in excess of the normal. The most probable explanation of these findings is that many of these patients with very high systolic pressures showed relatively low diastolic pressures. They belong to the group with arteriosclerotic hypertension in

TABLE 4 Data in Patients Twenty-Eight to Fifty Years of Age

STATUS OF PATIENT	NO OF PATIENTS	AVERAGE BLOOD	HIGHEST PRESSURE	AVERAGE BLOOD	LOWEST PRESSURE	LIFE EXPECTANCY	ACTUAL DURATION OF LIFE	DEFICIT
		SYSTOLIC	DIASTOLIC	SYSTOLIC	DIASTOLIC	yr	yr	yr
Living	20	220 6	121 7	160	96 7	29 4	18	11 4
Dead	12	255 7	126 7	175	94 2	26 0	15	11 0

years or younger. This group is of particular interest because it is patients of fifty years or younger who are usually regarded as favorable subjects for dorsolumbar sympathectomy. Of these, the 12 patients who have died had lived an average of fifteen years, or eleven years short of their life spans. The 20 still alive have lived an average of eighteen years, or again about eleven years short of their normal expectancy. They are, all but 3, normal people who are living normal lives without symptoms. They probably will live enough longer to raise the average length of life for the group to a much more favorable figure. A question that should be considered is whether or not the long-range results of surgical treatment can be expected to be of benefit to these patients.

Regarding the influence of sex it must be admitted that a group of 20 patients is far too small to justify any definite conclusions. However, in these 20 male patients the average life expectancy for 8 patients alive in 1947 was nineteen years and the actual duration of life fifteen and three-fourths years, and the average expectancy for 12 dead patients was nineteen and a half years and the actual duration fifteen and a half years. The deficit for patients in the former group was slightly over three years, and that for patients in the latter was four years. The duration of life was slightly longer than the average for the total of 100 patients. The age at which the condition was first observed was one year earlier than the average for the entire group.

The influence of the degree of hypertension on the prognosis is demonstrated in Tables 5 and 6

whom a loss of elasticity of the arteries, rather than degeneration of the arterioles, has led to excessive pulse pressures but not to marked organic damage other than cardiac hypertrophy.

This conclusion is upheld by a study of the facts presented in Table 6, which clearly indicate the unfavorable influence of a high diastolic pressure. In exactly 50 patients the diastolic pressure was found to have been, on one or more occasions, 120 or higher. In these patients the actual duration of life fell short of the normal expectancy by a considerably longer period than it did in the whole group. The other 50 patients, those whose diastolic pressure was never found to reach 120, showed,

TABLE 5 Influence of Systolic Blood Pressure of More than 250 \*

Dead	18	18 5	16 0	2 5

\*Among 1 living and 4 dead patients with systolic pressures of more than 300 the average life expectancy was sixteen and the actual duration of life sixteen and three-fourths years.

of course, figures for duration of life that were correspondingly more favorable than those of the total group. It is interesting to note, however, that the 50 patients who had diastolic pressures above 120 were on the average several years younger than those with the lower diastolic pressures, and that the actual time of survival in the two groups was approximately the same.

on their impressions gained in routine practice, but accurate studies in relation to the age of the patient and the type of hypertension present have not, it appears, been made

In still another respect previously reported studies of the prognostic significance of high blood pressure have failed to give the answer that is most needed. This is because the results are stated in terms that are difficult for the person untrained in

dealing with insurance and mortality statistics to interpret. What the physician wishes to know about the hypertensive patient for whose welfare he is responsible is how this condition will affect the length of the patient's life and his health and happiness during the years he has yet to live—in other words, what the relation of this person's probable span of effective life is to that to which, at his age, he is entitled.

The present investigation has been undertaken in an attempt to make a small contribution to the

supervene. In the group of 100 patients here reported retinal hemorrhages were very rare, and renal failure occurred in only 1 case, no case of malignant hypertension developed. For the purpose of the present study a systolic pressure of 180 or a diastolic pressure of 100 was regarded as evidence of excessive hypertension. The records were reviewed and the first hundred patients who were found to have had a recorded pressure of this degree or higher, and who were alive eight years or more afterward, were selected.\* Although many other patients with excessive hypertension of eight years' duration or longer have since been observed, it was recognized that by limiting the study to the patients who were seen earliest, the group would contain only cases in which a long follow-up study has been possible. Of the 100 patients, 90 were found to have had excessive hypertension prior to 1932, the remaining patients having first been observed in 1934, 1935 or 1936. In only 3 cases is the condition of the patient unknown at the present time. These 3 patients are reported as of their last recorded examination.

The average survival time was compared with the average life expectancy of all persons of the same age and sex†. The group then was divided

mass of information that will be needed before an adequate answer to this question can be given. It consists entirely of a review of the records of private patients seen since 1914. With a view to finding out what happens to patients with excessive hypertension that is definitely not of the progressive, malignant type, patients were chosen in whom the condition had existed for at least eight years. Eight years without progression was regarded as evidence that malignant hypertension would not

into three parts: the living, the dead, and the physically incapacitated. The patients then were reclassified according to age, sex and degree of hypertension,—both systolic and diastolic pressures being ascertained,—so that the influence of these factors on length of life could be deduced.

The patients in this group were first studied in 1944. The results are recorded in Table 1.

In the three years that have passed since this earlier tabulation, 20 patients have died. At present there are 47 persons still living, and 53 who have died. Tables 2 and 3 give the main facts concerning the whole group. When another ten years have elapsed only a few of the patients will, in the normal course of events, still be alive. At that time a more final judgment regarding ultimate prognosis will be possible.

It is evident from these tables that the average person of the group lives out almost his entire life span. When the various factors that influence the

†On the basis of tables for males and females presented by Dublin.<sup>11</sup>

Further investigation of this subject should involve the collection of a sufficiently large number of cases to make statistical studies really significant. This could be accomplished by the collaboration of a large number of physicians who have practiced twenty-five years or longer.

It is suggested that when the physician is confronted with a patient who is not over fifty years old and in whom he finds excessive hypertension, frequent examinations should be made for evidence of progression, especially for the signs of retinal, renal or cardiac damage. In the absence of such evidence it is believed that resort to surgery may well be delayed.

THE ECONOMICS OF INFANT AND CHILD NUTRITION\*

NATHAN B TALBOT, M D,† C C Koo, M D,‡  
WALTER W PICK, M D.§ AND SHIRLEY L WELLS¶

BOSTON

THE recent change in the world food situation from one of apparent relative adequacy to one of obvious deficit invites a brief review of the economics of providing infants and children with an adequate diet. In this connection total calories and protein appear to deserve the most consideration. Moreover, requirements for these two com-

ponents must be considered together because the protein needs of the growing child within certain limits are inversely proportional to the total caloric intake. This is due in part to the fact that the amino acids of dietary protein are needed and used for energy when calories from nonprotein sources are insufficient.

Table 1 sets forth the allowances for total calories and for protein recommended by the Food and Nutrition Board of the National Research Council in 1943. Experience in this clinic leads us to believe that these caloric allowances are approximately correct.<sup>2</sup> On the other hand, studies carried out both here and elsewhere<sup>3-8</sup> suggest that the recommended allotments of protein may be appreciably in excess of actual requirements under conditions of ample caloric intake. Assuming, therefore, that the recommendations of Table 1 are ample, the following considerations appear pertinent.

The daily recommended allowances for an average five-year-old child weighing 18 kg are 1600 calories and 50 gm of protein, providing 90 total calories and 2.8 gm of protein per kilogram of body weight. Theoretically, this food can be made up exclusively of vegetable nutrients or can be comprised of a mixture of vegetable and animal substances. When the caloric allotment is provided entirely by a mixture of such vegetable substances as wheat, corn meal, oats, potatoes, beans, peas, soybeans and carrots (Table 2), the protein intake is 75 gm, or 4.2 gm per kilogram of body weight per day. Even if 30 per cent of the calories come from a mixture of oranges, peaches, apples, tomatoes and cabbage and the remaining 70 per cent is derived from the substances mentioned above, the protein intake is about 64 gm, a value in excess of that recommended in Table 1. These data and experience with diets for metabolic ward patients indicate that, quantitatively speaking, it is difficult to feed a child

This leads to a comparison of the actual survival time of these patients considered without reference to their life expectancy (Table 7). The deficit—that is, the number of years by which this survival time falls short of normal life expectancy—for each group is also shown in Table 7, which demonstrates that the various factors discussed (age, sex and degree of hypertension) do not cause a marked variation in the actual duration of life. Although older people tend to live up to or beyond their normal life expectancy, this is because their life expectancy is shorter. Their average duration

—findings that are typical of malignant hypertension.

The most frequent cause of death in these patients is cardiac failure. A cerebrovascular lesion is the next most common terminal event.

The younger the patient at the time when the hypertension develops, the less likely he is to live out his full life span. Even in the young group (age fifty and below) the average length of life is over fifteen years (about eleven years below their expectancy). This is the age group in which dorso-lumbar sympathectomy is usually recommended.

TABLE 6 Influence of High Diastolic Blood Pressure

Dead	30	21.7	14.6	7.1	23	16.6	14.7	1.9

of life is about the same as that of the younger group. It is, of course, true that as the 47 people who are still alive (30 of whom are in apparent good health) continue to live on, the average duration of life for the whole group will lengthen. One may say, then, that the prognosis in hypertensive patients of the type discussed is actually more favorable than the figures indicate. The shortest duration of life recorded in the whole series, after the discovery of the hypertension, is nine years, and the longest twenty-five years.

SUMMARY AND CONCLUSIONS

Hypertension, even of an excessive degree, that has been present eight years or more and is not associated with well established cardiac or renal

For the malignant type of hypertension this operation is certainly of great value in delaying the fatal issue. With fifteen years or more of life ahead of him, however, it is questionable whether a person with the nonprogressive, nonmalignant type of high blood pressure should be subjected to such a radical procedure.

The present study does not indicate that the type of hypertension under discussion carries a poorer prognosis for males than it does for females. The group is too small to make this conclusion definite.

The degree of hypertension is important in relation to the diastolic pressure only. People with very high systolic pressures and relatively low diastolic pressures (the arteriosclerotic type of hypertension) survive appreciably nearer to their

TABLE 7 Actual Duration of Life and Deficit in All Groups

GROUP	LIVING PATIENTS	DURATION OF LIFE	DEFICIT	DEAD PATIENTS	DURATION OF LIFE	DEFICIT

Diastolic pressure over 120	20	17.8	6.2	30	14.6	7.1
Diastolic pressure under 120	27	16.2	3.8	23	14.7	1.9

disease usually does not indicate a poor prognosis. In fact the patient usually lives to within three or four years of his normal life expectancy.

Such hypertension does not commonly develop into the malignant type. In this series no case of such development was noted. It is not associated with marked arteriolar changes, evidenced by retinal hemorrhages or edema, or with renal damage

normal expectancy, on the average, than those with high diastolic pressures.

Regardless of sex or age or whether or not the diastolic pressure is below 120, this study indicates that these patients will probably live from fourteen to nineteen years. When the 47 patients now living have finished their lives, the figure will probably be considerably more favorable.

Moreover, many vegetables are of relatively low protein and mineral content, and some are deficient in certain essential amino acids. Hence it is only by careful selection and planning that an adequate vegetarian diet can be devised. For practical purposes, therefore, it is usually much easier to provide adequate nutrition with diets containing some animal nutrients. Milk is well suited both economically and nutritionally to this purpose. When only 10 per cent of the total calories are provided by milk, nearly 0.5 gm of protein and 16 mg of

\*Calculations based on average yield of calories per acre and per 100 man hours given in Tables 2 and 3

calcium per kilogram of body weight are supplied by the milk alone. Because milk is relatively inexpensive to produce, its inclusion to this extent raises the total cost of feeding relatively little (38 per cent) above that calculated for an all-vegetarian regime.

A further illustration of the economics of prescribing diets made up of different proportions of

calories (about 100 per kilogram) of body weight and water (150 cc per kilogram). However, because of variations in the amounts of milk and sugar used, the protein, fat and sugar allowances of each formula are different. For purposes of comparison, values for human milk are given at the bottom of the table.

Formulas A and B correspond closely to those commonly prescribed. When compared to human milk, it is seen that they provide about twice the quantity of protein taken by a breast-fed baby. The same thing is true of such minerals as sodium, potassium, calcium, chloride and phosphorus, the concentrations of which are three or more times greater in cow's than in human milk<sup>12, 13</sup>. Even Formula C, the cow's milk content of which is about half that commonly recommended, yields more protein and minerals than an equivalent volume of human milk. Yet this formula approximates the recommendation of Powers<sup>14</sup> that between 10 and 20 per cent of the total calories come from protein, 15 to 30 per cent from fat and 50 to 70 per cent from carbohydrate and the daily requirement of 2.2 gm of protein per kilogram of body weight reported by Levine<sup>15</sup>.

The relative costs of these formulas are estimated in the right-hand section of the table. It is to be noted that there are two columns under "cents," one of which is computed on the basis of whole milk and the other on the basis of evaporated milk. Formula C costs from one third to one half less than Formulas A and B, whether the measure of cost be monetary, acres of land or man hours of farm labor.

It is possible to make an approximate comparison between the costs of cow's milk vs human milk for infant feeding. It appears that human milk is produced with high efficiency (more than 90 per cent)<sup>16</sup>. If, therefore, a mother derives the

†Based on values given in Tables 2 and 3 in addition to chain-store prices in Boston on December 29, 1947 (fresh milk \$0.22, evaporated milk diluted to whole-milk strength \$0.125 per liter and sugar \$0.20 per kilogram).  
‡Assuming that extra food required for milk production is derived entirely from the vegetable nutrients listed in Table 2.

vegetable vs animal nutrients is provided by infant formulas. Table 5 presents information concerning the composition and costs of three arbitrarily selected cow's milk formulas that theoretically might be fed an infant weighing 4 kg. Each of these provides the same allowance of total

extra calories and other nutrients necessary for milk production from appropriate vegetable-fruit nutrients similar to those illustrated in Table 2, the cost in acres and in man hours of farm labor is roughly half that of Formula C. On the other hand, if she obtains these extra calories by drinking cow's

enough calories from a mixed diet without at the same time giving him at least 2 gm of protein per kilogram of body weight daily. Incidentally, cereal-vegetable-fruit diets yielding 1600 calories can also contain over 600 mg of calcium, an ample amount.<sup>2</sup>

So far as is known, there is no objective evidence that mixed cereal-vegetable proteins are quali-

ty is used to raise a mixture of the various animal proteins listed in Table 3, the yields of calories (214,000) and of protein (10 kg) are reduced to approximately 20 per cent of those derived from the mixed vegetables and fruits.

Re-expressed in terms of the productivity of 100 man hours of farm labor, the average yield in the

†Excluded from averages.

tatively inadequate. That such regimes are at least compatible with survival is attested by the fact that the poorest peasants in southern Italy have lived on corn meal, green stuffs and olive oil and have done so for generations.<sup>10</sup> Meat in the form of fat pork was taken three or four times a year. There was no milk, cheese or eggs in their dietary. In China the diet is also largely vegetarian. It becomes of interest, therefore, to calculate the relative costs of substituting animal for vegetable

form of the vegetable-fruit nutrients exclusive of sugar is 4,400,000 calories and 220 kg of protein. In the form of animal nutrients, the average yield from the same effort is about 640,000 calories and 28 kg of protein, or but 15 per cent of the productivity described for vegetables and fruit.

These data are reconsidered in Table 4, which presents calculated approximate costs of feeding a five-year-old child for an average day with vegetable-fruit vs animal-nutrient types of diet. It

nutrients or of adding extra animal-protein-containing foods to the vegetable regime. Tables 2 and 3 provide a basis for comparison.

When an average acre of land is used for raising the mixture of vegetables and fruits mentioned above, the average yield per acre is 1,325,000 calories and 49 kg of protein (Table 2). If an acre of land is used for raising sugar, the yield of calories is relatively much larger (6,600,000), but the protein yield is zero. By contrast, when an average acre

can be seen that the use of animal instead of vegetable-fruit nutrients greatly increases the costs of feeding. Viewed in these lights it seems that to include animal nutrients in the diet of children—and incidentally, of adults—may be more of an economic luxury than a nutritional necessity. Actually, as McCollum<sup>11</sup> has said, it is possible to make a fairly satisfactory diet of foods derived entirely from vegetable sources. But it is not easy to do so because vegetable foods tend to be bulky.

## BOSTON MEDICAL LIBRARY

## Report of the President\*

IN accordance with a long established custom it is my privilege to submit my second annual report as president of the Boston Medical Library.

Since our last annual meeting the active participation of the Massachusetts Medical Society in the affairs of the Library has become a fact. Every member of the Massachusetts Medical Society in good standing is now a Society member of the Library entitled to all the rights and privileges, except the right to vote, which by virtue of our charter is vested solely in the fellows. The Society allots \$5 00 of each member's dues toward the maintenance of the Library.

In view of this response to our appeal it seemed right and proper that the Society should have some voice in the management of the Library. Accordingly a special meeting of the Corporation was called, and the by-laws amended, to increase the membership of the Board of Trustees from twelve to sixteen, the Massachusetts Medical Society being invited to appoint four of that number. This invitation was accepted by the Council, and the president of the Society has appointed four trustees to serve one, two, three and four years respectively. Hereafter one new member will be appointed yearly. The additional income received will enable us to enlarge our personnel and increase our service.

Although we are grateful for this financial aid, we are still more grateful for the increased interest in the Library and hope that it will mean a much greater use of its resources by the members of the Society.

We have continued our efforts to put our house in order. Many volumes have been transferred to the Deposit Library in Cambridge. Many duplicates have been sold. Much remains to be done, but with the increase in our personnel we hope to progress steadily. The trustees have authorized the Librarian and the Director to enlarge our staff and several new members have already been appointed, but the reorganization must necessarily proceed slowly because of the lack of properly qualified persons to fill the positions.

We are greatly hampered by lack of stack room—five tiers of stacks in the fireproof ell have never been installed. The space where the stacks should be is now partially filled with volumes on temporary shelving on temporary scaffolding. This makes proper servicing a difficult if not an almost impossible accomplishment. If we are to give adequate service

these stacks and the service elevator must be installed. This will entail an expense of about \$75,000. How this can be financed is one of the many problems that confront us. It has been suggested that we solicit voluntary contributions, or that we borrow the money and set up a sinking fund to amortize the loan. I request that this be given serious thought.

In considering our financial setup it must be remembered that nearly two thirds of our invested funds are held in trust, the income only to be used for special purposes. Thus, we are committed to purchase rare books, or books on special subjects. We need a much larger unrestricted endowment to purchase current periodicals and volumes. Thanks to the care of the Treasurer, our funds, such as we have, are in excellent condition.

A certain portion of our income must be set aside each year for maintenance and repair of our building. Various repairs are imperative, and much painting needs to be done. The periodical room, which has never been finished, should be put in proper condition as soon as possible.

Very few fellows have resigned, scarcely more than the usual number. This is very gratifying. The fellows constitute the legal corporation of the Library. They are the custodians of its building, its books and its funds. They elect its officers and a majority of its trustees. This corporate body should be larger than it is now, so that the responsibility of this valuable institution may be shared by a large group. The additional income will also help. It may be possible in the future to provide more privileges for the fellows. I hope that each of us will propose one or more fellows during the coming year.

We are again grateful for the devoted services of the Librarian and the Director and our faithful staff. They have accomplished much under trying circumstances.

The Librarian will present a more detailed report on the present condition of the Library and his plans for the future. The number of visitors to the Library is increasing, and much more interest is apparent among the medical profession.

We are far from our goal, but with the hearty co-operation and support of the fellows and the new Society members, we have great hopes for the future.

WALTER G PHIPPEN

\*Presented at the annual meeting of the Boston Medical Library April 26, 1948.

milk, the costs are increased about fivefold and become comparable to those of Formula A

### DISCUSSION

The foregoing analysis sets forth some approximate information concerning average economics of human nutrition. It does not take into account variations in the agricultural potentialities of various geographical areas. Nor does it consider the important though less readily defined factors concerned with the flavor of food, the pleasure of eating and the influence on morale of palatable meals. A consideration of vitamins also has been omitted, though with the exception of vitamin D and possibly of riboflavin, vegetarian diets that are adequate in calories and protein appear to be satisfactory in other respects.

This information is of no moment to peoples who can afford what they want. It is of potential importance only when thrift is a necessity. The data presented provide no basis for recommending that animal be discarded entirely in favor of vegetable nutrients. On the other hand, they suggest that, when survival depends on getting enough to eat, due thought be given to the wastefulness of recommending more than minimal essential allowances of the animal type of nutrient.

Unfortunately, extensive data defining the minimum requirements of normal infants and children for protein, either animal or vegetable, are not available. In most of the published studies of protein requirements, the allowances of total calories were increased or decreased in approximate proportion to the protein allowances. Under these circumstances changes in nitrogen balance could have been due to changes in caloric intake as much as or more than variations in protein intake. Studies carried out in this clinic on healthy children two to ten years old suggest that when the caloric intake is ample, no improvement in the nitrogen balance is obtained by the daily administration of more than 2 gm of mixed protein per kilogram of body weight.<sup>8</sup> More detailed information of this type should be of value especially regarding infant

feeding in areas where cow's milk is scarce. For example, the same quantity of cow's milk dispensed as Formula C (Table 5) would feed one and a half times as many infants as it would dispensed as Formula B and nearly two and a half times as many as it would dispensed as Formula A.

These findings give some scientific substance to the Chinese proverb "20 ounces of chicken costs 20 pounds of rice."

### SUMMARY AND CONCLUSIONS

A brief survey of the approximate, relative costs of feeding infants various types of formula and children cereal-vegetable-fruit diets vs diets of equal caloric and protein content containing animal protein and fat is presented.

When thrift is necessary it is wasteful to feed babies by bottle or to provide more than minimal essential allotments of the animal-protein type of food for older children and adults.

men who lived long by using it. The single edition of this work was printed in 1484.

A third book was a treatise on fevers, thrice printed before 1501 and frequently in the sixteenth century. All the incunabula editions are in the Library. Another book is *De pulsibus, urinis et egestionibus*, 1487 and 1497, both editions being in the Library.

His best known work is on baths and mineral springs, printed in Ferrara in 1485. There are three incunabula editions, of which the Library has two (1485 and 1496). The book was probably written before 1450 and later revised before his death in 1462. A work on physiognomy exists only in manuscript. A vernacular text on gout, possibly taken in part from his *Practica* was printed in 1505. Both in the work on physiognomy and in that on baths, Savonarola showed originality, his *Practica* and other medical writings appear to be ordinary treatises of their time.

Three books, illustrating the spirit and practice of medicine in the sixteenth century, were also added in 1947. The first is by a priest from Steinhelm who combined in one volume three of the most popular and widespread beliefs of his time — astrology, physiognomy and chiromancy. The book was published in 1522 in Strassburg and was frequently reprinted for the next one hundred and fifty years. Three Latin printings were needed the first year, and the text was soon set in German, English and French. The *Chiromantia* of John ab Indagine, or von Hagen, was one of the most popular books north of the Alps. John ab Indagine, a humanist who was not afraid to attack scholastic theology, was a friend of a fellow priest, Otto Brunfels, the herbalist. Some even thought him a Lutheran, and he, like Savonarola, sought the greater tranquillity in letters. He was not a great man, but a stern and resolute face stands out on the title page of his book (Fig. 2). His works reached England through the books of Fabian Withers.

The medieval and Renaissance practitioner was fond of one-volume libraries, something he could slip in his saddle-bag and turn to when faced with any occasion — medical, surgical, astrologic or even spiritual. Such is the *Collectanea Medica* manuscript of 1450 in our Library, the *Articella*, mentioned above, and the *Artzneybuch*s of later dates. A good example of the last is the one issued at Nuremberg in 1549 (Fig. 3), consisting of medical treatises of practical interest, including obstetrics and a dental tract.

The third book is on old age and how to prolong life beyond the short span common in the sixteenth century. The most noted book of this type was *De La Vita Sobria* of Luigi Cornaro, first published in Padua in 1558. Cornaro lived to be one hundred years old, but Thomas Philologus of Ravenna, also called Tommaso Rangoni, whose book, *De Vita Hominis Ultra CXX Annos Protrahenda*, the Library acquired in 1947, tried to prolong human life beyond

one hundred and twenty years. Thorndike tells us that Philologus began writing prognostications as early as 1515, taught logic at Padua and then astronomy. He lectured at Bologna, became physician to Cardinal Grimani, a public teacher of astrology at Rome and finally a popular professor at Padua, where "enthusiastic students carried him around town on their shoulders." The town echoed with his name and it was written all over the walls of

buildings. In turn Philologus endowed a college at Padua for thirty-two students from his home city of Ravenna and restored churches and other buildings at Venice. In 1575 he published a tract on syphilis. The edition of *De Vita* in the Library was published in Venice in 1550 (Fig. 4).

One other accession is of particular interest. The anatomist, Remmelin, wrote a famous atlas, the *Catoptrum Microcosmicum*, showing the human figure in a series of superimposed plates. The book was first issued with a Latin text in 1613 and was frequently reprinted. The Library has an edition of 1660. The book also appeared in German, and the Library has the 1632 edition, printed at Ulm. In 1947 we acquired an English edition, *A survey of the Microcosme, or the Anatomy of the Bodies of*

## Report of the Librarian\*

IT IS again the privilege of the Librarian to present to the Corporation of the Boston Medical Library his annual report—in this instance, his tenth accounting of the state of the Library. In general the year has been a good one, with a marked increase in use of the Library both by our readers and by those who borrow material from us. The addition of two persons to the staff has provided more and prompter service than we ever were able to offer before. The Library has continued to grow in size as well as in usefulness. In spite of inadequate stacks, poor lighting, unfinished rooms and an untidy duplicate storehouse, our books are still intact and our periodical files in reasonably good shape, and our treasures can be made available to all who knock on our door with scholarly intent and reasonable patience. The Director, whose knowledge of our Library affairs and medical librarianship in general is unexcelled, continued to serve, even on Sundays, those who most needed his help.

### SERVICE TO READERS

Our readers consist of the fellows, members of various classes, including the newly formed Massachusetts Medical Society members, students who are not members and the general public. We serve all, without distinction so far as the use of our collection is concerned in Holmes Hall. Many of the users, over 9000 in 1947, were neither fellows nor members, coming from classes not supporting the Library financially. To this service to the public the Library is dedicated.

The attendance in 1947 was not quite so large as in 1946, but nearly up to the average of the prewar years. Of more importance is the use of the collections, it was larger in 1947 than in any year in our history, with the exception of one year when the Harvard Medical School Library was closed and many of its readers came to the Boston Medical Library for their bookish inspiration. Thus we went ahead in 1947 of our prewar circulation rate, with the use of 42,638 books and periodicals, compared with 38,266 in 1946—a healthy sign in a growing institution. At the same time the interlibrary loans to other institutions doubled, by far the greatest use of our Library in this department ever experienced.

The Library, moreover, increased in size by over 2500 volumes and nearly 4000 pamphlets. Owing to increased personnel we were able to prepare and bind more than 1600 periodical volumes, 1000 greater than in 1946. Thus, the Library furnished more material to its readers in 1947 than ever before, and this service was rendered by our old staff and the two additional and very welcome new members.

\*Read in part at the annual meeting of the Boston Medical Library April 26, 1948.

### ACCESSIONS

Seven incunabula were added to the Library in 1947, bringing our total to 696. They included *De anima* of Alexander of Aphrodisias, three other copies of which were listed by Stillwell as in libraries in the United States. Alexander was a Greek philosopher and commentator on the writings of Aristotle who lived in Athens at the beginning of the third century A.D. Sarton describes him as "the greatest scientific thinker of the time." A general study of Alexander's work in science is badly needed.

Another addition was the second printing of the *Articella*, a popular collection of the writings of Galen, Hippocrates and others, widely used by students in the fifteenth century. The Library has two other incunabula editions of this book, now having three of the six recorded printings before 1501.

The Library has an unusually complete run of the first printings of the works of Michele Savonarola, the physician and grandfather of the Dominican martyr, Girolamo Savonarola. Two further editions were added in 1947, the rare *De aqua ardenti*, published in Pisa in 1484 (Fig. 1), and a copy of *De febris*, issued at Venice in 1496.

Giovanni Michele Savonarola, physician to the famous Este family of Italy, was born at Padua in 1384 and died in 1462, neither date being clearly fixed. All his works were originally circulated in manuscript and only printed posthumously. The most popular was his *Practica de aegritudinibus*, edited by Alexander Sermoneta and Joannes Aquilanus, first published as a printed book at Colle di Valdelsa by Bonus Gallus in 1479, seventeen years after the death of the author. Before that time eager students were forced to use manuscripts, some with faulty copy and all of them both scarce and expensive. With printing, the floodgates of learning were open: two more editions were demanded before 1501, and the book was frequently reprinted in the sixteenth century, filling a need long after the author's death.

The *Practica* is Savonarola's chief medical work and was probably finished by 1440, for a manuscript edition is known of that date. It was written at Padua, where he received his degree of doctor of medicine from the University on August 20, 1413, and later taught and practiced. After 1440 he became physician to Niccolò III, marquis of Este. After the death of Niccolò he served Lionello and then Borso d'Este in the same capacity. The *Practica* deals, according to Lynn Thorndike, with the causes and cure of disease, prognostics, the physician's personality, foods and medicines and their effects, the last being largely taken from Avicenna.

In *De aqua ardenti* Savonarola accepts alcohol as an essential medicine and recounts the lives of noted

voted to the Library as he was to his chosen profession of orthopedic surgery and to Tufts College Medical School, where he served as dean from 1913 to 1922. One of his avocations was the history of medicine, and naturally he turned to the Boston Medical Library as a source of inspiration, believing at

and it was Cushing who wrote in a letter to his father, dated January 31, 1892

Painter I like very much. He is slow, but hangs on to everything he gets. He hails from Great Barrington, Mass. and is a great big solid whole-souled creature such as one likes to meet.

They both went to Massachusetts General Hospital, where Painter was associated with E. H. Bradford, Robert Lovett and the other brilliant orthopedic pioneers of the time. He was surgeon-in-chief at the Carney Hospital for many years.

Even before he was chosen librarian in 1929, Dr. Painter had long been interested in the Boston Medical Library and had served on a number of commit-

FIGURE 3 Title Page of *Arzneibuch* (Nuremberg, 1549)

the same time that he might contribute, at least in his modest way, to the work of the Library.

Dr. Painter was born in Grand Haven, Michigan, May 19, 1869. Coming from an old Virginia family, he enjoyed the reunions of the Painter family held at Pulaski, Virginia, a delightful region between the Blue Ridge and the Allegheny Mountains. He received the degree of A. B. in one of the earlier classes of the newly founded Johns Hopkins University in 1891. After four years of study at Harvard Medical School he received the degree of M. D. in 1895. In his class were many men whose names are well known to the members of the Boston Medical Library. They include Joseph Capps, Arthur Chute, Amory Codman, Harvey Cushing, Elliott Joslin, Timothy Leary, William Robey and Franklin White, many of whom were destined to make their names known not only in this country but also abroad. Harvey Cushing was closely associated with Charles Painter during his four years in the Medical School,

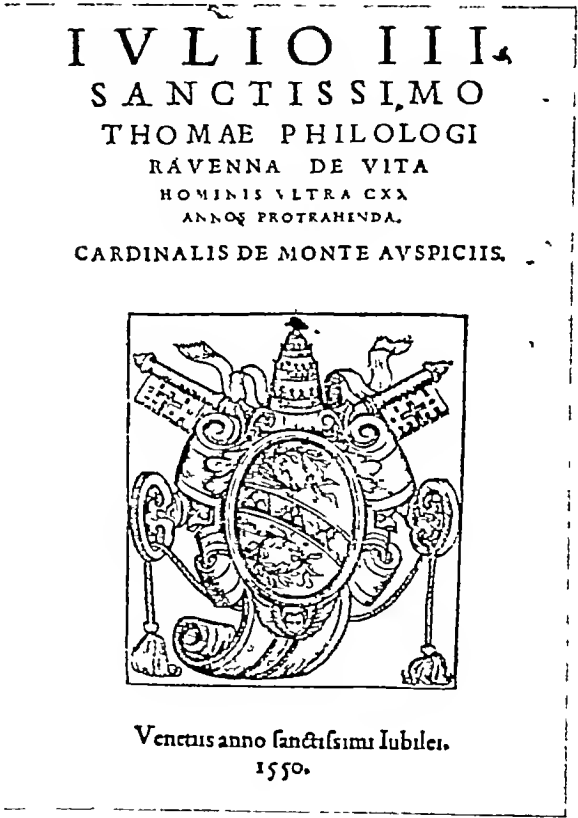

FIGURE 4 Title Page of *De Vita Hominis Ultra CXX Annos Protrahenda*, by Thomas Philologus (Venice, 1550)

tees. His literary endeavors, moreover, led to the creation of a chair of the History of Medicine at Tufts College Medical School, a position occupied by him for a number of years. He edited the *Yearbook of Orthopedic Surgery* and served for a long period on the editorial board and briefly as the editor of the *Journal of Bone and Joint Surgery*. He was president of the American Orthopaedic Association in 1915-1916.

*Man and Woman*, the gift of one of our trustees, 1905 Dr Farlow augmented the work of the first printed in London in 1695 All three books have the librarian, Dr Chadwick, who had started the Li

fine, but fragile, superimposed plates in good condition

#### CHARLES FAIRBANK PAINTER

Dr Charles F Painter died suddenly at his home, January 6, 1947. He served as librarian of the Boston Medical Library from 1929 to 1937, following Dr John W Farlow, who had been librarian since

library on its modest career in 1875 only to see it develop into a medical institution of considerable proportions by 1905. It was Chadwick who saw us into our present house. Dr Painter, in turn, continued the fine standards set by his predecessors. He carried the Library, moreover, through a period of decreasing financial support, without materially reducing the service to its members. He was as de-

a fine account of our first president, with many of the pictures and quite a few of the facts furnished by the Library

### FUTURE

The Librarian plans to fill our space in the Deposit Library with little-used material in 1948. At the end of 1947 about a third of the shelves were in use. As a result some reorganization of our duplicate collection will be possible, but no major change can be considered until our additional stacks are in place. Personnel are to be added as soon as suitable persons can be found. Publishing projects

are under consideration. An addition to Farlow's *History* covering the period from 1918 to 1948 might be a fitting volume or a catalogue of our sixteenth-century books, similar to our published list of incunabula. Our Golden Jubilee, moreover, will occur in 1950, for on Monday, October 18, 1875, in two ground floor rooms at No 5 Hamilton Place, the Boston Medical Library began its reorganized existence, with Dr E H Brigham in charge. At that time Dr O W Holmes was the president, and Dr J R Chadwick the librarian.

HENRY R. VIETS

## MEDICAL PROGRESS

### PHYSIOLOGY\*

HEBBEL E. HOFF, M D,† AND H. J. SCOTT, M D ‡

MONTREAL, CANADA

ON NOVEMBER 22, 1947, the *British Medical Journal*<sup>1-4</sup> celebrated with a special issue the ninetieth birthday of Sir Charles Sherrington, whose *Integrative Action of the Nervous System* had been reprinted earlier in the summer as a feature of the seventeenth International Physiological Congress, the first to be held since the end of the war.<sup>5</sup> Both were gracious tributes to one of the great philosophers of the nervous system, a worthy member of that long and unbroken descent of scientific greatness represented by presidents of the Royal Society. Like that of Boyle, one of the founders of the Society, his philosophy has been anchored in the day-by-day experience of his laboratory, and theories, built on experiment, served to direct the experimentation of the next day, for, as Boyle said, these matters "should not be barely asserted, but explicated and proved."<sup>6</sup> Few neurophysiologists have been a part of so many of the fundamental movements in their field, we can expect only Galen perhaps who was its founding father, for Sherrington saw more clearly than any that the simple reflex, with its afferent and efferent arcs keeping action always under control of environment, furnishes the clue to the operations of the complicated region of the nervous system, where always the basic connection of afferent and efferent, sensory and motor functions is continued. Thus Sherrington was the great master of the reflex, and no one has surpassed him in his description of its nature and in biologic purposiveness, in fact Sher-

ington has brought to a close a whole era in neurophysiology, that of the reflex. Standing thus at the end of one classic development he participated equally importantly in the beginnings of two others: the study of cortical function and the investigation of the intimate physiology of unitary components of biologic patterns—indeed, it was in recognition of his investigation of the "single unit" that he shared with Adrian the Nobel Prize in Medicine in 1932. Finally, when the laboratory could no longer claim him, he has turned his rich experimental background to reflexions of "Man on his Nature,"<sup>7</sup> carrying out to the fullest extent the obligation of the physiologist to attempt always the synthesis of total and unit behavior—to explain the whole in terms of its parts.

So Sherrington has given a philosophy of neurophysiology, but he has furnished too the language and the tools of the work that lies ahead, as witness the happy phrase "synapse" and that inexhaustible source of experimentation, the decerebrate cat. Above all he has had the remarkable faculty of transmitting to others something of his own outlook. In no small measure this has been because of his acute sense of historical perspective, his willingness to learn from Aristotle and Galen, Fernel and Descartes, Marshall Hall and Goltz, and his ability to frame his own work against the background of the past. Few are the centers of neurophysiology where his pupils, or his pupils' pupils, are not to be found, and none where his influence has not reached. It is not inappropriate therefore to review some of the more significant advances in neurophysiology, in which his influence may be seen at work.

\*From the Department of Physiology McGill University Faculty of Medicine.

†Joseph Morley Drake Professor of Physiology McGill University Faculty of Medicine.

‡Research Assistant, Department of Physiology McGill University Faculty of Medicine.

The Library loses a friend of many years' standing. Although heavily engaged in the active practice of surgery he was always ready to devote time to Library activities. His heart, moreover, was truly in the field of literature as well as in the practice of medicine. He was essentially a scholar both of orthopedics and of medical history. Indeed we can truly proclaim with his contemporary, Harvey Cushing, Dr. Painter was a "solid whole-souled creature such as one likes to meet."

### LIBRARY ACTIVITIES

#### Addresses and Meetings

The Librarian addressed the Section of Neurology and Psychiatry of the New York Academy of Medicine on "The History of Neurology in the Last Hundred Years," in New York City on March 11, 1947, the session on the History of Medicine, American Medical Association, on "American Medicine in the Massachusetts Bay Colony," at Atlantic City, June 11, and Massachusetts Historical Society on "Benjamin Waterhouse on Luigi Cornaro's *Long and Healthful Life*," Boston, October 9.

The Director and the Librarian attended a farewell dinner to Dr. Henry E. Sigerist, former professor of medical history at Johns Hopkins University, in May in New York, the meetings of the American Association for the History of Medicine and the annual session of the Medical Library Association, held at Cleveland the same month, and the meeting of honorary consultants to the Army Medical Library in Washington in October. The Librarian also visited the Medical Library of Duke University, the Welch Medical Library in Baltimore and the Medical Library of the New York Academy of Medicine during the year and made numerous visits to the Army Medical Library, both in Cleveland and Washington, as chairman of the Committee on Historical Medicine of the last institution.

In April Miss Genevieve Miller, assistant editor of the *Bulletin of the History of Medicine*, was tendered a dinner before her address to the Boston Medical History Club, and in October Mr. Geoffrey Keynes, the distinguished British surgeon and bibliographer, was a guest of the Librarian in Boston.

#### Book Reviews

About 250 books, received from the *New England Journal of Medicine*, were reviewed in 1947, either by short notes (about 100) or by longer, critical reviews. The short notes were mostly written by Mr. Ballard, and the reviews by some of our 96 devoted reviewers, whose names are listed semiannually in the *Journal*. The Library is indebted to the *Journal* for the books and to the reviewers who carefully evaluate the current literature and, in most cases, courteously deposit the book in the Library for the benefit of our readers.

#### Exhibits

The exhibit of the "Ether Demonstration" was held over for the first half of 1947 and was followed by an exhibit of material relating to the "History of the Boston Medical Library," showing the earliest catalogues of 1807-08, pictures of the various buildings used for the Library on Hamilton Place, Boylston Place and The Fenway, "The Want Book," or "Periodical Deficiency List" of Dr. James Read Chadwick and other memorabilia, arranged by Mr. Ballard.

#### VARIA

In 1947 the second edition of *A History of Medicine*, by Arturo Castiglioni, edited by Dr. E. B. Krumbhaar, was published. This monumental work, of particular importance for its discussion of the Italian influence on the Renaissance, was brought up to date by the inclusion of events in medicine occurring during the last six years since the first edition. A new history of medicine, also published in 1947, by Cecilia C. Mettler is distinctive, since it is arranged by subjects instead of in the usual chronologic form. Both are fundamentally reference books, although they cannot always be relied upon for bibliographic details. Other books of more than passing interest published in 1947 were *The Development of Modern Medicine*, by Richard Harrison Shryock, an expanded text of a book first issued in 1936, *Studies and Essays in the History of Science and Learning*, issued on the occasion of George Sarton's sixtieth birthday in 1944, but delayed in printing by the war, *Nicolaus Pol Doctor 1494*, by Max H. Fisch, *The Doctor in Oregon*, by O. Larsell, and of particular interest to the Boston Medical Library, *Amiable Autocrat: A biography of Dr. Oliver Wendell Holmes*, by Eleanor M. Tilton,

inhibitory activity must be exerted at the motor neurone or its synapses. The latency of inhibition of the two neurone arcs is, as Lloyd has shown, extremely short, no more perhaps than a millisecond. This demands in turn that the central pathways for such inhibition must be in themselves very short. To cover these requirements Brooks and Eccles have recently brought forward a novel and most ingenious electrical hypothesis of central inhibition that forms a logical counterpart to Eccles's electrical theory of central excitation. According to this hypothesis the inhibitory volley operates by subliminally stimulating an internuncial cell sending a short axon to the motor neurone to be inhibited. On the soma of the internuncial neurone will be created a local synaptic potential that will act as a sink into which current will flow from the axon and inactive areas of the soma and dendrite of that cell. There will therefore be a considerable outflowing current from the synaptic ending of the axon of this cell, which will in large part penetrate the postsynaptic membrane of the motor neurone. There it will produce a localized region of anelectrotonus, and as a result the excitability of the region will be depressed. One may now assume (and there are good histologic grounds for so doing) that the surface of the motor neurone is liberally covered with hundreds of synaptic endings, and postulate that inhibitory endings are more or less uniformly dispersed. If excitatory impulses are alone discharged the local responses will spread and fuse, generating the discharge of an all-or-nothing impulse. If, however, inhibitory impulses arrive simultaneously with or slightly before the excitatory impulses each excitatory focus will be surrounded by a zone of raised excitability, which will as it were isolate the excitatory influences and prevent their growth and fusion into a propagated impulse.

### THE CEREBRAL CORTEX

#### *Somatic Afferent Areas*

Interest in the motor area of the cerebral cortex has been so keen and discussion over it has waxed at times so hot that the equally important function of the cortex as an afferent receiving station has at times been neglected. But those who have thought deeply of the plan of the central nervous system have seen in the development of the higher centers an opportunity for the renewal of the effective association of afferent and efferent fibers that forms the plan of the simple reflex arc. Walshe<sup>14</sup> wrote of this

There we have presented to us a conception of the nervous system in which the entire edifice is reared upon two neurones, the afferent root cell and the efferent root cell. The two form the pillars of the fundamental reflex arc and on the junction between them are superimposed, mediately or immediately, all the other neural arcs, even those of the cerebral cortex itself.

As Adrian<sup>15</sup> stated, "purposive acts, therefore, must be moulded like the movements of walking, by the controlled afferent patterns which are set up as the act progresses." Sherrington<sup>5</sup> wrote

The reactions of receptor organs which respond to stimuli from a distance tend especially to have large cortical representation. These receptors tend more than others to control the skeletal musculature of the creature *as a whole*. The contribution made by the cerebral hemispheres to the solidarity of the motor creature is largely traceable to their bringing to bear on other reflexes the unifying influence of the reactions of the distance receptors. Remembering these conditions it need not surprise us that the distance receptors more and more exert preponderant directive influence over the whole nervous system. To say this is to say no more than that the motile and consolidated individual is driven, guided, and controlled by, above all organs, its cerebrum. The integrating power of the nervous system has in fact in the higher animal, more than in the lower, constructed from a mere collection of organs and segments a functional unity, an individual of more perfected solidarity. We see that the distance-receptors integrate the individual not merely because of the wide ramification of their arcs to the effector organs of the lower centers, they integrate especially because of their great connection in the high cerebral centres. Briefly expressed, their special potency is because they integrate the animal through its brain. The cerebrum itself may be indeed regarded as the ganglion of the distance-receptors.

So too, indeed, thought Descartes, who neglected the spinal cord as a mere bundle of nerve fibers and placed the whole of reflex activity in the cerebrum. Here began all the motor nerves of the body and here were projected all the sensory fibers (according to Descartes a single fiber could, of course, perform both motor and sensory functions, its motor through the flow of animal spirits in its hollow axis cylinder, and the sensory by a fibril running in the core of the fiber). These were so arranged that their spatial pattern within the brain reproduced the spatial distribution of the receptors from which they originated, so that as he wrote of the eye, "if we see any creature come toward us the light reflected from his body paints two images, one in each eye and these two images beget two others by intercourse of the optic nerves in the interior superficies of the brain that look toward its cavity." The demonstration of the histologic basis for such point-to-point projection from retina to cortex constitutes one of the triumphs of neurohistology. Recently, however, the method of physiologic neuronography has been applied to the afferent projection systems, particularly by the group at Johns Hopkins, where Woolsey<sup>16, 17</sup> and a series of collaborators have meticulously traced pathways of action potentials set up by the natural stimulation of some isolated peripheral receptive zone. On the basis of these studies it is now possible to make cortical maps of somatic afferent representation of the body surface and of acoustical representation in the auditory area that show precise point-to-point representation. In 1941 Adrian<sup>18, 19</sup> reported studies of a similar nature that have opened up a completely new aspect of

## THE NATURE OF REFLEX ACTION

Sherrington was one of the first to appreciate the significance of Cajal's first studies with his new modification of the silver-staining technic, the whole of his reflex doctrine is based on the assumption of the validity of the neurone doctrine that Cajal established. This lack of protoplasmic continuity between neurones focused attention on the point at which one axon establishes communication with another neurone, and so important did this region become that he established a name for it—the synapse. To him the fundamental characteristics of reflex behavior stem from the particular physiology of the synapses, and their anatomic pattern. Here there developed states of excitation or inhibition, "CES" and "CIS," whose algebraic sum determined whether the neurone discharged or remained silent, and he determined with care their time courses in several reflexes. But although electrical recording was not neglected at Oxford (the string galvanometer had been enlisted early as an aid in the precise timing of muscular contraction), it has remained for his pupil Eccles to make the most complete study of the intimate nature of synaptic transmission in simple reflexes.

Sherrington<sup>5</sup> described the reflex as follows:

There is the co-ordination which a reflex action introduces when it makes an effector organ responsive to excitement of a receptor, all other parts of the organism being supposed indifferent to and indifferent for that reaction. In this grade of co-ordination the reflex is taken apart, as if separable from all other reflex actions. This is the *simple reflex*. A simple reflex is probably a purely abstract conception, because all parts of the nervous system are connected together and no part of it is probably ever capable of reaction without affecting and being affected by various other parts, and it is a system certainly never absolutely at rest. But the simple reflex is a convenient, if not a probable fiction.

Almost precisely in this sense has Lloyd<sup>8, 9</sup> defined the simplest of all reflexes, the proprioceptive stretch reflex. This reflex has its simplest expression in the knee jerk in the "spinal" man or animal, in a more highly developed form it is the fundamental component of reflex standing. Many earlier physiologists had indeed doubted that the knee jerk was in fact a reflex, its extremely short latency seemed to preclude this possibility.<sup>5</sup> Measuring the central latency of the reflex, Lloyd found that it was in fact so short that impulses entering via dorsal roots must have elicited a response in the ventral-horn cells without the mediation of an internuncial neurone. The stretch reflex is thus the simplest of all reflexes, involving only the direct influence of receptor upon effector neurones. This simple reflex is, however, organized, anatomically and physiologically, in relation to reflexes from other muscles acting at or across the same joint, reinforcing and being reinforced by some, and inhibiting and being inhibited by others, to form a functioning whole, which is the unit of biologic organized activity, the myotatic unit.<sup>9</sup>

Eccles<sup>10-13</sup> has recently summarized the evidence that at a variety of regions of anatomic discontinuity, such as in the synapses of the sympathetic ganglions, at the somatic myoneural junction and at the synapse of the spinal reflex, transmission occurs by virtue of the electrical influence exerted by activity in the presynaptic tissue upon the structure on which it impinges. Studying the electrical behavior of these structures under normal circumstances and when transmission is diminished or suppressed by appropriate drugs, such as curare in the neuromuscular junction and deep anesthesia in the reflex, Eccles has found evidence for the postulate that the passage of the impulse down the terminal portions of the presynaptic fiber causes flows of current in and out of the postsynaptic membranes that act precisely as an externally applied electrical stimulus. As the impulse first approaches the synapse in the presynaptic fiber it creates across the junction a momentary anelectrotonus, or the state produced at the positive pole of an external current applied to the tissue. This anelectrotonic state momentarily depresses the excitability of the postsynaptic tissue and delays its eventual response. It can account almost entirely for the phenomenon of synaptic delay. As the impulse in the presynaptic fiber reaches and occupies the whole of the synaptic expansion, the current is reversed and flows from the immediately adjacent postsynaptic membrane into the activated region of the synapse. This creates in turn at the postsynaptic membrane a catelectrotonic focus, which spreads exponentially over the surface of the neurone, out of its most intense area there grows a local response of the neurone. If by virtue of the concentration of synaptic endings the catelectrotonic focus is large enough in area and intense enough in degree, out of it or out of the local response itself there can develop a full blown action potential that will sweep over the excited cell. If neither the local response nor the exponentially propagated electronic potential is large enough to set up a propagated impulse, the slowly decaying potential will nevertheless alter the threshold of the neurone so that a second impulse arriving at that or nearby synapses and in itself incapable of creating a propagated impulse in a resting neurone might find the threshold now low enough to evoke a response. This is the basis for summation.

In the recent studies on the mechanism of central inhibition that Brooks and Eccles<sup>11, 13</sup> have carried out, one sees "a return to the original concept of Sherrington, that there are converging on motor neurones two sets of impulses, those exciting and so tending to cause the reflex discharge of impulses and those directly opposing this influence." This concept is a necessary consequence of Lloyd's demonstration that the stretch reflex involves only a two-neurone arc, for since this reflex can be inhibited by appropriate afferent stimulation, such

pathologic physiology of the human conditions. Recent studies bring this objective much closer to realization. The first of these is the discovery by Magoun and Rhines<sup>27</sup> of an inhibitory mechanism in the bulbar reticular formation. Stimulation within the reticular substance lying ventromedially in the lower part of the bulb was found to inhibit spinal-cord reflexes and decerebrate rigidity and induced cortical motor responses. Such inhibition was bilateral from either side of the reticulum, although at lower thresholds some ipsilateral inhibition could be identified. A variety of evidence showed that this bulbar-depressor center probably receives activating impulses from a suppressor area (4S) of the cortex, from the cerebellum and from the basal ganglia.<sup>28</sup>

Further work by Bach and Magoun<sup>29</sup> confirms the impression gained by earlier experimenters that much of the facilitation of the stretch reflex that is responsible for decerebrate rigidity descends to the spinal cord via the vestibulospinal tract and originates in the vestibular nuclei. But Rhines and Magoun<sup>30</sup> find that another important source of facilitation descends by a more laterally lying tract from a widespread center for facilitation extending from the thalamus, the sub-hypothalamus, the central gray and tegmentum of the midbrain, the pontine tegmentum and the bulbar reticular formation. Stimulation in these regions facilitates the reflexes of the lower center and augments the effect of cortical stimulation.<sup>30</sup> In the decerebrate animal much of this region has been removed, leaving to the vestibular system the greatest responsibility for maintenance of decerebrate rigidity, but in the intact animal this newly discovered facilitatory center assumes greater importance, particularly in the facilitation of phasic movement. Rhines and Magoun point out that it is essential to recognize that this facilitatory area is the same that on more intense stimulation will yield motion. This motor system, in all probability, maintains the almost normal motor activity of the decorticate cat and permits even the decorticate infant monkey to maintain a simple type of locomotion and muscular activity.

Ward<sup>31</sup> has shown that in the "decerebrate" rigidity resulting from small doses of sodium cyanide or other agents, neuronal activity is suppressed first at the cortical level and then at successively lower levels as the concentration of the agent increases. By implanting electrodes in the bulbar suppressor center he has shown that decerebrate rigidity appeared at the time when failure of nervous activity in centers activating the suppressor region produced a deprivation paralysis of this center and thus permitted the unrestrained activity of the facilitatory center to be expressed in the appearance of decerebrate rigidity.

Taken as a whole these studies form a logical complement to those on stimulation and

ablation of the premotor cortex and serve to establish the concept of a nonpyramidal projection system mediating complex reflex reaching and grasping acts, movements of neck and shoulder-girdle musculature, rhythmic movements of the lips and of the tongue, as in sucking and licking, rhythmic movements of the upper extremities, behavior pattern and patterns of progression as well as inhibition of posture and other reflexes of the spinal cord.<sup>32</sup> Discovery of these brain-stem facilitatory and suppressor regions permits an explanation of many states of atonia and diminution of movements seen in man and in experimental animals, such as the observations of Keller<sup>33</sup> demonstrating atonia rather than decerebrate rigidity after large lesions in the region of the pons, the fixed, immobile and mask-like facies seen in the monkeys with hypothalamic lesions observed by Ranson,<sup>34</sup> the akinesia of cats with large caudal hypothalamic lesions observed by Bard<sup>35</sup> and others and the production of mutism or reduction of facio-vocal activity after damage of the periaqueductal gray matter and tegmentum.<sup>36, 37</sup> All these may be interpreted as resulting from damage to brain-stem centers for facilitation. Most suggestive of the function of the bulbar suppressor center is the observation of Wagley<sup>38</sup> that a section of the reticulospinal fibers in the cord produces spasticity without paralysis.

This view of the function of the extrapyramidal system forms the logical counterpart to the concept of the pyramidal system as a predominantly motor apparatus, developed largely to mediate the control of skilled motion. This surely stems from Descartes, for although Galen recognized that the brain was the source of the spinal cord and the peripheral nerves, his more general concept was of the brain as a pool from which the animal spirit flowed to be distributed by the spinal cord acting more or less as an irrigation-distributing system. Descartes elaborated the hypothesis that the brain was linked to each muscle by isolated nerve fibers originating from the cavities of the brain in a spatial arrangement reconstructing the body. The mind or reflexes generally evoked motor response appropriate to the circumstances by opening these nerve endings to the animal spirits in the manner of an organist manipulating a keyboard. His concept was almost precisely that of Walshe,<sup>14</sup> who, arguing in quite the opposite direction, wrote as follows:

It would seem therefore that we may look upon the pyramidal system as an internuncial, a common pathway by which the sensory system initiates and continuously directs, in willed movements, the activity of the nervous motor mechanisms. The pyramidal system of itself initiates nothing and to speak of it as "responsible for" this or that category of movement is to ignore the force and motor power of its activities. It is simply the channel through which pass the impulse volleys by which willed movement is activated and continuously moulded by controlling cortical afferent patterns of excitation.

the problem of cortical localization. He found that a representation of different parts of the body's surface could be mapped out on the sensory area and that in general the receiving area of the cortex is concerned with parts of the body surface that are most closely related to the outside world. Thus, in the rabbit the mouth parts and in the cat the claws and the dorsal and lateral aspects of the forelimbs are most importantly represented, the face area is large in the dog, and the representation of hand and face important in the monkey.

Most significantly, however, Adrian found that the digits of the cat had a double representation, impulses from the claws and the ventral side of the toes appearing in a second area lying posterior to the face and extending back into the ectosylvian gyrus. A similar double representation has been found in monkey and man.<sup>20</sup> The somatic area I is of course the previously recognized afferent area in the postcentral gyrus of man and its homologue in other mammals. Somatic area II in the monkey lies on the upper back of the sylvian fissure between the auditory areas of the lower sylvian banks and the face subdivision of somatic area I. It is significant that the pattern of representation of body surface in the postcentral gyrus coincides closely with the pattern for distribution of motor points in the precentral gyrus. Representation in the second sensory area is not so precise, the largest responses being produced by stimulation of the extremities of the limbs, the snout and the tail of the monkey. Both contralateral and ipsilateral representation is found, the former being about twice as strong as the latter. There is differentiation of face, arm and leg centers within this area that overlap extensively in the rabbit, less so in the cat and least in the monkey. There are data to suggest that the two areas have separate projections into the cortex although they are apparently interrelated at the cortical level in addition. Rassmussen and Penfield<sup>21</sup> have surveyed over three hundred and fifty stimulation records in man to find 8 patients in whom the presence of a second sensory area would account for unexpected responses for which there was previously no explanation. In these patients subjective evidence of sensation was elicited when the brain was stimulated at the foot of the sensory motor strip just above the sylvian fissure.

Woolsey and Walzl<sup>16</sup> and Ades<sup>22</sup> found a second auditory area lying immediately ventral to the primary auditory cortex in the cat. A point-to-point projection of the cochlea was found in the primary projection area, each cochlea being represented bilaterally in the primary projection area with approximately equal ipsilateral and contralateral representation for each cochlea. The focal area for the basal end of the cochlea was found at the upper end of the anterior ectosylvian sulcus, with the apical end of the cochlea represented just

behind the upper end of the posterior ectosylvian sulcus. The second auditory area lies immediately ventral to the primary auditory cortex, but it is organized in a pattern inverse to that of the primary system with the basal end of the cortex represented caudally and the apex rostrally. Finally, evidence for double representation of vision has also been presented.

Clues to the significance of this re-representation of the three major sensory areas have not yet been found, but Woolsey emphasizes the fact that it appears to be a fundamental principle of organization in other spheres. He points out that there is evidence that the cerebellar receiving areas are also double, that there are apparently slow and fast groups responsible for conduction of pain, that, as Adrian<sup>23</sup> has shown, the electric response of the human eye to the flash of light can be divided into a rapid and a slow component, and that, as pointed out below, a re-representation of the motor area also exists. It is obvious that these studies open up a whole new field for investigation, the detailed analysis of the relations of these areas to each other by direct intercortical communications or through corticothalamic associations has been started<sup>24,25</sup> and gives promise that the future will see an understanding of the association of afferent and motor systems at the cortical level with a degree of completeness that now characterizes the interaction of these two systems at the simple monosynaptic reflex level.

### *Cortical Control of Posture and Movement*

Sherrington's discovery of decerebrate rigidity brought into relief the concept of levels of integration developed by the clinical neurologists, according to which the developmentally higher centers were capable of inhibiting as well as exciting spinal-reflex centers. Damage to higher centers resulted not only in a deprivation paralysis of some functions but also in release-phenomena from discontinuance of the normal braking action. The continued validity of this concept finds expression in modern as well as in the older literature—for example, in the observations of Wang and Lu<sup>26</sup> on the development of the tadpole. These authors observed that the first integrating mechanism to develop in the tadpole is a spinal system for repeated reaction to a single stimulation. Somewhat later there developed in the rostral half of the hind brain a center that inhibits the spinal mechanism, reducing its spontaneous activity and limiting the reaction from external stimulation to a short response instead of the prolonged response of an earlier stage.

The many similarities between decerebrate rigidity and spastic states in man following lesions within the central neuraxis have encouraged the hope that from closer analysis of decerebrate rigidity in animals, clues might be found to the

machinery by which the synthetic powers of that cortex are made possible. The motor cortex seems to possess, or to be in touch with, the small localised movements as separable units, and to supply great numbers of connecting processes between them so as to associate them together in extremely varied combinations."

CASE RECORDS OF THE  
MASSACHUSETTS GENERAL HOSPITAL

Weekly Clinicopathological Exercises

FOUNDED BY RICHARD C CABOT

TRACY B MALLORY, M D, Editor

BENJAMIN CASTLEMAN, M D, Associate Editor

EDITH E PARRIS, Assistant Editor

CASE 34291

PRESENTATION OF CASE

A fifty-eight-year-old woman entered the hospital because of a right-upper-quadrant mass. One week before admission the patient had sudden onset of severe constant pain in the right upper quadrant, which lasted, diminishing somewhat in intensity, for two days and then disappeared only to return again quite suddenly two days before admission. This time the pain was severe enough to require morphine but lasted for only one day. With these attacks there were no chills, fever, nausea, vomiting or jaundice. There were no

genitourinary symptoms or bowel symptoms either with the attacks or during the months before admission. However, during this period the patient noted a small weight loss of undetermined amount. For many years certain articles of diet such as Coca-Cola, ginger ale and sweets caused frequency of urination and burning, and "rich foods" caused indigestion. Seven years before admission, following an attack of right-sided pain, she was told that she had a kidney stone. Two years later, following a period of weakness and nausea of indefinite duration, a parathyroid tumor was removed at another hospital. At about the same time a non-functioning gall bladder was found by x-ray examination. The patient's mother had died of carcinoma of the rectum, and a sister had died of carcinoma of the uterus. Physical examination disclosed a well developed and well nourished woman, the important physical findings being limited to the abdomen. In the right upper quadrant there was a smooth, slightly tender, apparently cystic mass approximately 15 cm in diameter, which appeared attached to the liver. The blood, urine and stool examinations were within normal limits, as were the nonprotein nitrogen, total protein, calcium, phosphorus, alkaline phosphatase, prothrombin time, bromsulfalein test and cephalin-flocculation test. A blood Hinton

Willis<sup>39</sup> adopted much the same view from Regius one of Descartes' students

Moreover, as we have affirmed, that the Instinct for the performing of Motions is brought altogether through the Nerves from the Head to the Muscles, and as every Trunk of the same Nerve, being oftentimes broken into many shoots, variously distributing them, sends it to many destinated Muscles, it may very well be doubted how the animal Spirits, conveying the Symbol of the motion to be performed with a certain choice, do actuate only these or those branches apart from other branches of the same, and do not indifferently enter all the branches or shoots of the same, to wit, as the blood passes through the Trunk of the Artery, and all its ramifications equally. The most Learned Regius, that he might solve this knot, supposes in the Nerves some little doors, like to those which are found in musical Organs, the apertures whereof admit the Spirits to these or those parts especially, the rest being shut up. But he ought to have shewn, if not the little doors themselves, yet at least by what instinct and by whose direction sometimes these, sometimes those are locked up, and others opened. But in truth, this may rather be said, that all the shoots of the Nerves and lesser branches remain distinct and singular among themselves from the part to which they are inserted, even to their beginnings, so that a peculiar tract of Spirits or way of passage lyes open, from the Brain and its medullary Appendix, to every Muscle and nervous part, for in truth, although the Nerves, according to their beginnings, may seem to arise from the greater Trunks, yet it will easily appear, if you shall open the trunk of those branches, that in them many little Nerves, only like hairs, for the sake of a better conduct, are collected together in the same bundle, yea, the coverings being separated, you may follow oftentimes the little Nervulets, and those single to the respective parts and members, to which they are destinated

More than anyone else it has been Sherrington who has been responsible for the development of a modern hypothesis of punctate localization by his repeated demonstration of the response to cortical stimulation and by publication of maps showing a regional representation of the body musculature in the precentral gyrus. It was obvious to Sherrington<sup>40</sup> that "the individual movement, elicited by minutely localized stimulations are, broadly speaking, fractional in the sense that each, though co-ordinately executed, forms, so to say, but a unitary part of some more complex act, that would, to attain its purpose, involve combination of that unitary movement with others to make up a useful whole." Sherrington concluded that the cortex is not merely a selector of patterned movements established at lower levels but a center for the integration of afferent and efferent impulses where both are represented in minute degree and where the possibilities for the interaction of the two are vastly expanded.

The large variety of partial, though discrete and in themselves perfect, movements of separate portions of the bodily framework, evocable by localised point-to-point stimulation of the motor cortex, and the multiform combinations which these assume under cortical reaction and the right mutual associations of the cortical motor points which the physiological phenomena of "facilitation" and "deviation of response" reveal, are suggestive. They lead to the supposition that from movements of locally restricted parts—e.g., movements of a finger or a limb-joint (movements themselves discrete and individually separable in the motor cortex)—the upbuilding of larger combinations varied in character and service

able for purposes of different and varied kind, prehensile, defensive, locomotor, mimetic, masticatory, deglutitional, orientational (in von Monakow's sense), etc., is one of the main offices performed by the motor cortex. The functional properties of this cortex seem specialized for that end. It appears at first sight surprising that a motor nervous organ relatively so high as is the cerebral cortex in the nervous hierarchy, where the power to deal with large integrated complexes of the motor machinery might be expected, exhibits on actual examination a representation, still more or less discrete, of relatively small and "partial" movements. And in the motor cortex this discrete "representation" of small local items of movement, each highly co-ordinated with others yet separably elicitable, instead of becoming less evident with ascent to the higher types of hemisphere, becomes more so. Thus, it is more evident in cat and dog than in rabbit, more evident in the Macaque than in cat or dog, in baboon than in Macaque, in gibbon than in baboon, and in the chimpanzee, orang, and gorilla than in gibbon. It would seem that in order to preserve the possibility of being interchangably compounded in a variety of ways successive or simultaneous, these movements must lie, as more or less discrete and separable elements, within the grasp of the organ which has the varied compounding of them. To draw an analogy merely illustrative, the synthesis of the proteins of the body requires that certain metabolic organs must have, lying at their hand, the numerous amino-acid constituents of proteins, for that purpose the food proteins, split up into constituent chemical subgroups, more or less freed one from another, are presented to the synthetic organs for varied re-grouping in the re-synthesis which follows. The motor cortex appears to be par excellence a synthetic organ for motor acts. How does the motor cortex obtain these fractional and partial movements on which work its powers of varied synthesis? Simpler co-ordinated elements, such as flexion of a single joint—e.g., knee or elbow—can be safely assumed to lie ready to its hand in the bulbo-spinal mechanisms. But the higher of the compounded movements which those mechanisms give tend, if judged from the spinal and decerebrate dog and cat, to be compounds exhibiting total flexion or total extension of a whole limb. In the limb movements evoked from the anthropoid motor cortex, flexion of one joint may go either with flexion or with extension of another. The motor cortex may therefore obtain the partial and fractional movements it so variously weaves together by, to a certain extent, breaking up compounds already constructed by lower centres. Such analytic power may be a property of its own, or of some other, perhaps subcortical, organ with which it keeps close touch. Such synthesis involves time adjustments as well as spatial adjustments. The bulbo-spinal axis also, of course, synthesizes motor acts. But the difference between the constructive planes of the two is considerable. Bulbo-spinal synthesis constructs in the main those locally restricted but co-ordinate movements which the cortical synthesis finds ready to hand as elements for it to work with. The bulbo-spinal organ taken as a whole does, even in types so high as dog and cat, synthesize in addition to the local elementary movements a not inconsiderable number of more complex ones, such as respiratory, defensive, and even locomotory. But comparison of the synthetic capacity of the bulbo-spinal organ with that of the motor cortex reveals a great excess of synthetic capacity in the latter, as evidenced by the variety and multiform scope of the motor acts and sequences it builds up. Especially is this so when it is borne in mind that many acts which, when naturally performed, are bilateral, are, when excited by stimulation of one motor cortex, essentially unilateral, indicating that the two motor cortices have to be regarded as in many respects a single organ when in natural operation. Together they form, in such an animal type as the anthropoid ape, an organ for synthesis of movements—and of postures—on a vast scale. Phenomena, such as "reversal of response," "facilitation," and "deviation of response," prominent in cortical responses, and accounting for the functional instability of cortical motor points, are indicative of the enormous wealth of mutual associations existing between the separable motor cortical points, and those associations must be a characteristic part of the

## DR MCKITTRICK'S DIAGNOSIS

Hydrops of gall bladder

## ANATOMICAL DIAGNOSES

*Carcinoma of gall bladder*

*Cholelithiasis*

## PATHOLOGICAL DISCUSSION

DR CASTLEMAN Perhaps the reason why the surgeon waited eight days was that the patient was sent in to Dr G G Smith as a urologic problem and it took a few days to have the general surgeons see her. Dr Richard H Sweet examined her. The mass was smooth and tender and felt to him like a hydrops of the gall bladder. He did not believe it was kidney. At operation he found that the mass was a large gall bladder adherent to the omentum and also to the transverse colon, where one could see it pressing against the hepatic flexure. It was inflamed, had a red, thick wall and extended down into the bed. In removal a good deal of grumous material came out, and when the mass was opened, it was found to contain large numbers of stones. In freeing up some of the adhesions it was discovered that there were several nodular areas in a portion of the fundus, which to Dr Sweet, looked suspicious of carcinoma. When finally examined, there were large, papillary-like masses projecting into the lumen of the gall bladder, which on microscopic examination proved to be an undifferentiated carcinoma. Several stones were present as well.

This case is interesting because seven years previously a Graham test had been positive. Had the gall bladder been removed at that time, I suppose that the cancer would have been prevented. Dr Joel Goldthwait of our laboratory looked up the cases of carcinoma of the gall bladder that were found at autopsy, and out of 12,000 autopsies in adults, he found stones in 12 per cent, and 3 per cent of the cases with stones had carcinoma of the gall bladder. The usual statistics are between 3 and 5 per cent.

DR JACOB LERMAN What correlation was there between stones and cancer?

DR CASTLEMAN Ninety-five to 98 per cent of cases of carcinoma of the gall bladder occurred in patients with gallstones. The incidence is very high and one wonders whether, if a patient shows a stone on x-ray study, the gall bladder should be removed. What is the experience of the surgeons? Do they always remove it?

DR MCKITTRICK That depends on the surgeon and the patient. I would have advised cholecystectomy in a patient with a pathologically obstructed gall bladder, which I assume she had seven years before admission. I should like to ask how many gall bladders are pathologic without

stones. If stones are demonstrated, I think the gall bladder should be removed.

DR CASTLEMAN The stones are not visible on the films in this case.

DR MCKITTRICK That is not unusual, even in a carefully done cholecystogram one may not see the pigment stones. That is why I wondered how often one sees a pathologic gall bladder without some form of concretion in it.

DR CASTLEMAN I should say that most of the really diseased gall bladders have stones.

DR MCKITTRICK That is the clinical impression that most surgeons have.

## CASE 34292

## PRESENTATION OF CASE

An eleven-year-old schoolboy was admitted to the hospital following attacks of acute spasmodic abdominal pain.

Five months previously he experienced a one-day episode of severe pain just below the umbilicus, coming in spasms and causing him to double up in bed. There was no nausea, vomiting or change in bowel habits. There were no chills, fever or bloody or tarry stools. Following this he resumed his normal activity with good appetite and no weight loss. Eleven days prior to admission the pain returned, and he was operated upon at another hospital. According to his mother, the appendix was not involved, but a "tumor of the cecum" was found and the operation was terminated without an attempt at resection. He convalesced uneventfully and was admitted to this hospital for diagnosis and treatment.

Physical examination was negative except for a recent right pararectus scar. No abdominal tenderness or masses were noted.

Examination of the blood showed 14.6 gm of hemoglobin and a white-cell count of 8700, with 57 per cent neutrophils. A urinalysis was negative. A stool specimen was guaiac negative. A barium enema filled the colon readily from rectum to cecum. The terminal ileum was not demonstrated. The appendix was not adequately visualized in the pre-evacuation study but was well filled in the post-evacuation films. It was movable and not remarkable in appearance. Along the medial aspect of the cecum at about the level of the ileocecal valve there was an extrinsic pressure deformity about 2.5 cm in diameter. This was best demonstrated with the patient prone.

On the fifth hospital day an operation was performed.

## DIFFERENTIAL DIAGNOSIS

DR LEO BURGIN By virtue of the previous laparotomy a good deal of the wind has been taken out of my sails. Such every-day possibilities as an

test was negative. An intravenous pyelogram showed a soft-tissue mass, 8 cm in diameter, on the right side of the abdomen with apparently no connection to the kidney. There was good renal function, and no stones were seen. A barium enema showed the same mass in relation to the superior aspect of the transverse colon but not intrinsic in the colon.

On the eighth hospital day an operation was performed.

### DIFFERENTIAL DIAGNOSIS

DR JOHN B MCKITTRICK: May we see the x-ray films?

DR JAMES J McCORT: The mass is present on the right side. Following a barium enema it is seen to cause a slight pressure defect in the region of the hepatic flexure. There is also a small diverticulum in this region, which is well demonstrated on the spot film. On the pyelogram one can see the mass extending below the inferior pole of the kidney and through the mass one can see the outline of the kidney clearly. There is no distortion or displacement of the calyces or pelvis. The mass itself is smooth and shows no calcification.

DR MCKITTRICK: The pain is characteristic of gallstone colic. It was severe, recurrent and in one instance required morphine. The patient did not have chills, fever or jaundice, and we have no evidence from the history that there was any inflammatory process going on. Indigestion is mentioned, but the history does not tell us how severe it was. This is significant in view of a later statement regarding a slight weight loss.

I believe that the urinary frequency attributed to Coca-Cola, ginger ale and so forth had nothing to do with the present episode. One cannot tell what the frequency means. The frequent passage of large amounts of urine after the ingestion of sugar should make one investigate the patient from the point of view of diabetes. In the past, she had renal stones, and five years later the removal of a parathyroid tumor. It would be interesting to know what prompted the search for the parathyroid tumor.

DR BENJAMIN CASTLEMAN: There is a letter from her doctor saying that he saw her because of a toxic thyroid gland. She was sent to the Peter Bent Brigham Hospital and seen by the late Drs Elliott Cutler and Soma Weiss. Apparently, the parathyroid tumor was discovered in the process of thyroidectomy, so that I do not believe that she had symptoms of hyperparathyroidism.

DR MCKITTRICK: I wondered if the history of kidney stones had stimulated the search.

DR CASTLEMAN: Dr Soma Weiss thought that the vomiting was due to the toxic goiter.

DR MCKITTRICK: The mass in the right upper quadrant was slightly tender, smooth and 15 cm in diameter, and appeared to be attached to the liver. This means gall-bladder disease until proved

otherwise. We are not given one item of important information about this mass. I would like to know whether it was fixed or movable and how long it had been present. The laboratory studies reported are negative. There is no bilirubin report, but I would anticipate this determination to be normal.

The only diagnosis that I can make is hydrops of the gall bladder. I am a little skeptical of this diagnosis because it appears too simple. Such a condition may develop painlessly, in fact, it usually does. It is due to obstruction by a stone in the lower end of the gall bladder or cystic duct, with distention of the gall bladder without infection. That is one reason why I wanted to know whether it was movable. The average hydrops is movable and may attain considerable size. In this case, there was enough tone left in the wall of the gall bladder to cause pain.

What should one consider in the way of differential diagnosis? There is always the question of carcinoma. I do not see how one can rule it in or out. The association of stones and carcinoma of the gall bladder is high, carcinoma of the gall bladder being almost always associated with gallstones. We have insufficient evidence, even with the weight loss, to make a diagnosis of carcinoma. Also, the diagnosis of carcinoma of the gall bladder is usually not made preoperatively, although at times one can legitimately suspect it. There are various lesions of the kidney that could present this picture, but they are fairly well ruled out by the preoperative examination. Apparently, in the mind of the attending physician, a lesion in the colon was also considered since a barium enema was done. It is entirely possible for lesions of the hepatic flexure to present themselves in this location and to appear to be fixed to the liver. We cannot rule out a lesion in the head of the pancreas. A cyst in the head of the pancreas can attain a large size and give the physical character of the mass described in this patient. I do not see how we can rule that in or out, but I do not believe the history is consistent with cyst of the pancreas.

Should we consider the common duct in our diagnosis? It is true that a large, distended gall bladder can occur in a patient with obstruction to the common duct in the absence of much or any jaundice. Usually, however, these patients have other symptoms that suggest common-duct disease, such as chills, fever and jaundice. A determination of the blood bilirubin would have helped in this regard.

The surgical service waited eight days to operate upon this woman. If my diagnosis is correct, she could have been operated upon much sooner. My diagnosis is stone impacted in the lower end of the gall bladder, with hydrops.

### CLINICAL DIAGNOSIS

Hydrops of gall bladder

terminal ileum in a nine-year-old child operated on for appendicitis

In the present case we have evidence of a lesion intimately associated with the cecum in a boy of eleven who appeared to be well otherwise. The lesion was responsible for colicky pain on at least two occasions. In the course of laparotomy it is described as a tumor of the cecum. I believe this lad had a duplication of the cecum.

May we see the x-ray films?

DR STANLEY M. WYMAN: The barium-filled colon on the large film fails to reveal the lesion described, but after evacuation there is a faint suggestion of irregularity of the cecum medially. The films taken during examination show a continual demonstration of a filling defect on the medial wall of the cecum. The fluoroscopist believed that this changed somewhat in contour during examination. This spot film taken after barium shows a faint suggestion of lobulation in that area. The ileocecal valve is not filled on any film so that one cannot say whether this is the ileocecal valve or the region adjacent to it. The well filled appendix is seen in this film and appears normal. The fluoroscopist's impression was that the mass was entirely extrinsic, but I think it is hard to exclude the possibility of an intramural lesion pressing on the lumen of the bowel.

DR BURGIN: The note said in effect that the deformity was better visualized when the patient was prone, suggesting that the weight of the lesion itself gave rise to it. That would be more evidence for a lesion outside rather than inside the bowel.

DR WYMAN: I was not sure about that statement, and I asked the fluoroscopist about it. He was not entirely certain in retrospect that that was so.

DR BURGIN: Since the patient had very little in the way of symptoms referable to disturbed function within the gastrointestinal tract, I am going to stick to my original diagnosis of enterogenous cyst of the cecum.

#### CLINICAL DIAGNOSIS

Benign tumor of cecum

#### DR BURGIN'S DIAGNOSIS

Duplication of intestinal tract.

#### ANATOMICAL DIAGNOSIS

*Duplication of intestinal tract (terminal ileum)*

#### PATHOLOGICAL DISCUSSION

DR RICHARD H. SWEET: I was called upon to perform the second operation in this case. The surgeon who performed the first operation is a competent surgeon in western Massachusetts but a close relative of the patient who decided against doing radical surgery on a member of his own family. When I talked with him and reviewed

the history the picture seemed most suggestive of intussusception of a transitory nature that relieved itself spontaneously. The surgeon described the tumor quite accurately as being very soft and having little substance. When I felt it, it was obviously not mesenteric adenitis. One could see normal lymph nodes. The appendix was free and uninvolved. The tumor felt as though it were part of the wall of the cecum, although it was very soft. Only when I removed it and had a chance to dissect the mesentery off a little bit and looked more carefully was I certain of its nature. I thought it was a soft, polypoid lesion of the bowel itself, but we performed a rather limited resection, removing the cecum and a portion of the terminal ileum.

DR TRACY B. MALLORY: The specimen removed showed a cyst, lying within the wall of the terminal ileum in immediate apposition to the ileocecal valve, with a relatively small internal diameter (7 mm), which was included in the muscular layers of the ileal wall. The content of the cyst was a pure mucous fluid, and the lining was quite smooth and looked like intestinal mucosa. That was confirmed microscopically. This is, I think, a very clear example of a so-called duplication of the intestinal tract. It was a small lesion that produced symptoms rather later in life than usual, probably because it remained so small. We thought at the time of examination that there was a slight degree of intussusception through the ileocecal valve. Dr Sweet perhaps had a better chance of determining that than we had.

DR SWEET: I could not be sure. It was obvious that it lay somewhat above and posterior to the ileum. I was surprised to learn that it was part of the ileum. It seemed to me that it was part of the cecum. There was no intussusception at the time of operation or at the time of the previous operation.

DR MALLORY: An intraluminal tumor is a very common cause of intussusception. A tumor exterior to the lumen of the bowel causes intussusception less frequently, but nevertheless could be a primary basis for intussusception or volvulus.

DR BENJAMIN CASTLEMAN: How else would you account for the colic, Dr Sweet, unless there was a degree of intussusception in the past?

DR SWEET: I am sure that is what this patient had. There is no other way to explain it—no inflammatory reaction and no narrowing of the bowel. The only way I could explain the obvious small bowel colic was that the bowel had become intussuscepted.

DR CASTLEMAN: Is that what Ladd and Gross say?

DR BURGIN: They mention distention of the cyst as a cause of pain. Of course these cysts are usually larger than the one described here. One in a lad seven or eight years of age, who I remember never to have had symptoms, was 1.5 cm

acute appendicitis, with or without abscess, Meckel's diverticulum and mesenteric adenitis are tossed out. One is led at once to the site of the lesion—the vicinity of the cecum. Our possibilities are still further narrowed by the demonstration of "an extrinsic pressure deformity about 2.5 cm in diameter." Rather than have some of our ideas dispelled at once by the roentgenologist, perhaps it might be better to proceed with the discussion and be refuted later by the x-ray films and Dr Mallory.

The first episode of pain is not particularly helpful. It sounds like colic. Many a youngster has had such a bout of colic owing to functional rather than organic difficulty. I presume that this episode was elicited by whoever took the history and may or may not be referable to the existing disease.

The attack of pain eleven days before admission must have simulated appendicitis. A laparotomy was performed, and a "tumor of the cecum" was found. That the appendix continued to be normal is attested to by the subsequent x-ray films, which revealed a freely movable organ, well filled with barium. Certainly the deformity described, the absence of fever, the normal white-cell count and the negative physical findings are against infection in the sense of an abscess, or other inflammatory process.

Could a mesenteric lymph node be large enough and close enough to the cecum to give such a picture? Certainly nonspecific mesenteric adenitis occurs without fever or elevated white-cell count. The findings at the previous laparotomy are against such a hypothesis. I doubt that lymph nodes ever reach such a size. Perhaps the surgeons can enlighten us on this point. I suppose one ought to consider lymphoma—of the Hodgkin's type with enlarged lymph nodes. The absence of a prolonged history of nodes elsewhere, of anemia and of intermittent fever seems to rule out this possibility. A tuberculous adenitis (tuberc mesenterica), especially if a number of lymph nodes were fused together, might give rise to a mass large enough to give the deformity shown by x-ray study. Pain is perhaps the most consistent complaint but need not be present. We have no information regarding the tuberculin test, nor is there anything to suggest tuberculosis elsewhere.

What of malignant tumors? Those inside the bowel would be associated with melena of varying degrees, anemia, loss of weight, nausea, vomiting and so forth. Cancer of the gastrointestinal tract is quite rare in childhood and when present is more likely to be in the rectosigmoid area. This patient presumably remained in good health after the first episodes of pain, cancer seems unlikely. The evidence offered is for a lesion outside the bowel. We may likewise rule out benign tumors of the gastrointestinal tract, adenoma, fibroma and so forth for those lesions would be expected to give rise to disturbed gastrointestinal function.

What about abdominal tumors outside the bowel? The most common malignant abdominal tumors in children are those connected with the kidney, such as embryoma, and those arising from sympathetic nervous tissue in the retroperitoneal space. These tumors occur earlier in life and are associated with an enlarged abdomen and palpable mass, usually in the flank in cases of embryoma, nodular masses are generally palpable in cases of neuroblastoma. The latter metastasizes early to liver, lung and bone. Signs of debility are generally present.

What other structures should we consider? Changes in the tissue adjacent to the cecum—the mesentery—might well be responsible for this picture. Bits of lymphatic tissue may become displaced in the mesentery and proliferate, and since no communication is available with the lymphatic system, cysts (so-called mesenteric cysts) are the result. These may occur anywhere in the mesentery either at the base or at the enteric border. Since they are not usually tensely filled, they tend to be flabby and, until they become large, may escape notice on abdominal palpation. In the typical case a painless, slowly enlarging abdomen is the only complaint. Symptoms of obstruction or abdominal pain may occur intermittently. Generally the cysts are large and freely movable. I can visualize such a cyst giving rise to this x-ray picture. However, because of its very flabby nature, one would expect an inconstant picture, which we assume was not present in the case under discussion.

There is another lesion that can arise in tissues adjacent to the cecum—or for that matter anywhere in the gastrointestinal tract. This is the so-called enterogenous cyst or, as such lesions are often called, duplication of the alimentary tract. Small outpocketings of intestinal mucosa occur regularly in the fetal alimentary tract. Some of these may fail to regress and become pinched off and give rise to an adjacent duplication. These duplications then secrete to a varying degree, sometimes to the point of pressure necrosis. In contradistinction to mesenteric cysts, these duplications are firmly adherent to the intestine and usually have a smooth-muscle coat of more than one layer. They may be large enough to be felt by palpation and often give rise to symptoms of colicky pain, partial obstruction and visible peristalsis. The pain may arise from distention secondary to excessive secretion within the cyst. Occasionally they press upon mesenteric vessels as they lie within the leaves of the mesentery and give rise to sloughing or bleeding of adjacent bowel. On the other hand, they may not give any symptoms for long periods. In fact Ladd and Gross\* report the incidental finding of a 12-cm duplication of the

\* Ladd, W. E. and Gross, R. E. *Abdominal Surgery of Infancy and Childhood*. 455 pp. Philadelphia and London: W. B. Saunders Co., 1941. P. 83.

by a few horses in rounding him up and branding him, and then putting him into a weaning pen in the fall. Cowboys think they work hard, but most of us would gladly trade jobs with them—the horse donates most of the foot pounds. During the ensuing winter some man energy is expended in feeding the steer hay while the snow is deep. The following summer his own legs carry him up into the mountain ranges, where he stores away all the  $\text{NH}_2$  groups and peptide linkages that are later recognized as beefsteak. Finally, a horse carrying a rider gathers him and his fellows together and takes them to the railroad, where the oxidation of carbon as coal (or oil) carries them to the stockyards. The energy of transforming him from a steer to a beefsteak is a complicated problem of industrial work, but it probably finds its analogue in Aroostook County through the sorting, grading, cleaning and sacking of the potato.

Furthermore the steer has availed himself of grass growing on land that generally cannot be used for anything else. If the steer does not eat the grass it is eaten by wild animals or else it goes to seed. If the steer eats it after it is ripe many of the seeds go through him unchanged and undigested but will grow new grass on the same pasture. In essence, although the steer meat requires 17 acres for 1,000,000 calories as opposed to the 0.44 acres for 1,000,000 calories of potatoes, that is not the whole story. There is in addition a difference in the energy expenditure required to produce the food in edible form and a wide discrepancy in the types of land that must be used to produce the two foods. Even though it requires 17 acres to produce 1,000,000 calories of beef it is quite conceivable that this amount of beef is produced with the expenditure of fewer calories than the 1,000,000 calories of potatoes and with considerably less depletion of the earth's resources. It thus becomes apparent that the gross figure of acres required to produce food does not wholly cover the subject of planning the economy of the United States or, indeed, that of the world. If 1,000,000 calories of good protein is to be obtained in the most efficient way all the other energy input factors must be measured, weighed and carefully accounted for.

## SHERINGTON'S CLASSIC CONTRIBUTION TO NEUROPHYSIOLOGY

LAST November 27, Sir Charles Scott Sherrington, dean of the world's physiologists, Nobel Laureate and author of *The Integrative Action of the Nervous System* (1906) quietly celebrated his ninetieth birthday. Sir Charles was very much alive, and the Physiological Society of Great Britain even more so, for they republished his famous monograph<sup>1</sup>—referred to by the author as “my rather elderly book”—and saw to it that appropriate notices appeared in the *British Medical Journal* and the *Lancet*. Best of all, Sir Charles wrote a “Foreword to 1947 Edition,” as brilliant a piece of writing as ever came from his pen—thoughtful, meaty, with a meticulousness of style long familiar to his devoted followers, whose contact with him in recent years has been largely through *Man on his Nature* (1940) and *The Endeavour of Jean Fernel* (1946). In crisp sentences he deals with some ambiguities that have arisen since 1906 and turns from the simpler forms of reflex behavior

The field of the psyche is entered. An old adage has it that to the trodden worm its own trodden self is the world's greater half. That anthropomorphic worm may typify ourselves to us, the “self” of each of us goes far to epitomize the integration we are now to look at. We can retain the scheme of spatial nervous arrangement we used before, this time, however, not mutilating the central organ, but keeping the animal—the human animal if you will—intact. The receptors at the starting-points of the nerve-thread we find now to be, by conspiracy with a psyche in the central organ, sense-organs. The full panel of the “five-senses” is in session, and by further collaboration with the psyche, a world of subject and object for the individual is in being. The individual has attained a psychological existence. Phases and moods of mental life accrue. Each waking day is a stage dominated for good or ill, in comedy, farce or tragedy, by a *dramatis persona*, the “self.” And so it will be until the curtain drops. This self is a unity. The continuity of its presence in time, sometimes hardly broken by sleep, its inalienable “interiority” in (sensual) space, its consistency of view-point, the privacy of its experience, combine to give it status as a unique existence. Although multiple aspects characterize it it has self-cohesion. It regards itself as one, others treat it as one. It is addressed as one, by a name to which it answers. The Law and the State schedule it as one. It and they identify it with a body which is considered by it and them to belong to it integrally. In short, unchallenged and unargued conviction assumes it to be one. The logic of grammar endorses this by a pronoun in the singular. All its diversity is merged in oneness.

Furthermore, “the body-mind liaison provides in a largely physical world the physical means of giving

## ACRES, MEN AND NUTRITION

A broader view of nutrition appears to be just around the corner. Although the Citizen's Food Committee long since abandoned the eggless Thursday and the meatless Tuesday, there is beginning awareness of a broader exchange of energy than that which exists between the A & P and the kitchen stove.

Dr. Fredrick J. Stare, in a recent issue of the *Atlantic Monthly*, calls attention to the fact that both meat and eggs must trace their energy origins to botanical processes, and that growing things in turn receive their energy from the sun, storing it in a convenient system based on the reversible oxidation of carbon.

Dr. Stare provides a table showing the number of acres of fertile land required to produce 1,000,000

calories of various foods. We see, for instance, that 1,000,000 calories of sugar requires 0.15 acres, as contrasted with 1,000,000 calories of beef, which requires 170 acres, of "fertile land." These figures are valuable, the concept is fundamental, and we are further indebted to Dr. Stare for the important work in nutrition that is being conducted at the Harvard Nutrition Laboratories under his able direction. Similar comparisons are to be found in the paper by Talbot and his associates published elsewhere in this issue of the *Journal*.

But are we not further forgetting the already forgotten man? The system of energy exchange that starts at the sun and ends with photosynthetic products on our tables (or in the mouths of Europe) involves another energy investment besides that of the sun's rays and the raw materials contained in the acres of fertile land. It is the energy of the working man who produces the food.

A contrast between the potato at 0.44 acres per 1,000,000 calories and the steer at 17 acres per 1,000,000 calories is instructive. Aroostook County farmers can tell a good deal about the energy required to raise an acre of potatoes. Each potato must be planted individually, cultivated, hoed, weeded and finally harvested by back-breaking effort. There may be machines that do this in 1948, but this argument considers the energy put into the potato patch by the men who work it rather than the energy from gasoline (even admitting that the products of the gasoline station also trace their origins back to plant life and solar energy). In the transport of the food energy of that potato from the seed to the table there is an expenditure of energy on the part of men — energy that the men in turn have received from other botanical products. In Aroostook County this manpower probably traces itself back to potatoes in large part, and it has been re-expended to harvest more potatoes.

A shift of attention to the steer reveals that the steer's mother, the cow, does most of the hard work. The bull, it is true, plays a brief but important role, thereafter disporting himself about the pastures in a carefree manner. After the calf is born he lives on his mother's milk for a few months, and the only other energy from animate sources that goes into raising him further comes from the energy expended

ges Radiological Society, succeeded in achieving a degree of publicity that, while it reflected no credit on a considerable number of physicians who perhaps had not heard of the Hippocratic Oath, nevertheless waked the "organized profession" into action

Let us hope that clean glasses will aid in a clearer view of all manner of rebates, kickbacks and other fee-splitting devices

### DEATHS

**DOUCETT** — Frederick L. Doucett, M.D., of East Weymouth, died on June 19. He was in his seventy-ninth year. Dr. Doucett received his degree from Tufts College Medical School in 1900. He was formerly a member of the Weymouth Board of Health.

A daughter, two brothers and a sister survive.

**FELCH** — Carrie I. Felch, M.D., of Boston, died on June 11. She was in her eighty-sixth year.

Dr. Felch received her degree from Tufts College Medical School in 1906.

A nephew survives.

**HOUGHTON** — Henry L. Houghton, M.D., of Boston, died on June 17. He was in his eighty-first year.

Dr. Houghton received his degree from Harvard Medical School in 1894. He was formerly president of Hahnemann Hospital, Boston.

His widow and a daughter survive.

**LINDSAY** — Joseph I. Lindsay, M.D., of Grafton, died on June 6. He was in his eighty-fifth year.

Dr. Lindsay received his degree from University of Vermont College of Medicine in 1888. He was formerly a member of the staff of Worcester Memorial Hospital and was a fellow of the American Medical Association.

A son, two grandchildren and a sister survive.

**MACCORISON** — Carl C. MacCorison, M.D., of North Berwick, Maine, died on June 4. He was in his seventy-first year.

Dr. MacCorison received his degree from Dartmouth Medical School in 1906. He was formerly medical superintendent of the North Reading State Sanatorium and was a member of the Massachusetts Medical Society and a fellow of the American Medical Association.

A brother and two sisters survive.

**PARE** — Francis M. Pare, M.D., of Worcester, died on January 28. He was in his forty-sixth year.

Dr. Pare received his degree from Georgetown University School of Medicine in 1931. He was a member of the staff of St. Vincent's Hospital and a member of the New England Obstetrical and Gynecological Society.

His widow, mother, father, two sons, a brother and two sisters survive.

**TORNEY** — George H. Torney, M.D., of Brookline, died on June 1. He was in his seventy-sixth year.

Dr. Torney received his degree from University of Pennsylvania School of Medicine in 1894. He was a member of the American Psychiatric Association and the New England Society of Psychiatry and a fellow of the American Medical Association.

His widow and two sons survive.

## MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

### THERAPY OF ROCKY MOUNTAIN SPOTTED FEVER

Therapy for Rocky Mountain spotted fever is still in the developmental stage. The following is a résumé of information received from Dr. John W. Oliphant, of the Rocky Mountain Laboratory, Hamilton, Montana.

#### *Para-aminobenzoic Acid (Paba)*

Since 1945, published and unpublished reports of 135 cases treated with para-aminobenzoic acid have been collected at the Rocky Mountain Laboratory of the United States Public Health Service. The average mortality for the United States for Rocky Mountain spotted fever is 20 per cent, of the patients treated with paba, 14 died — a mortality of 10.3 per cent. In 4 of these cases treatment was stated to have been begun too late. In 8 of the remaining cases, no beneficial results were observed. In 78 cases, some physicians thought the paba had been quite beneficial whereas others considered it of value but not to such a great extent. In 35 cases, no opinion was expressed. Statistical analysis of these 135 cases was not possible because complete information was lacking from many of the reports.

Flinn et al.<sup>1</sup> recommended a blood concentration of 30 to 60 mg. per 100 cc. Para-aminobenzoic acid in an initial dose of 4 gm. and 2 gm. every two hours results in blood levels of 5 to 10 mg. per 100 cc. Some patients respond well to this dose. The two-hour interval of medication is necessary because of the rapid excretion of the drug in the urine. Continued administration for at least two days after the temperature has returned to normal is recommended to prevent relapse.

Para-aminobenzoic acid is relatively insoluble in water but has a solubility of about 1 gm. per 20 cc. in 5 per cent sodium bicarbonate solution. The bicarbonate may be useful in preventing nausea and acidosis. Paba is available in powder or tablet form. The sodium salt is soluble and may be used orally or intravenously. It comes in 0.5-gm. tablets, in sterile vials containing 4 gm. of salt and in ampoules containing 1 gm. of salt in aqueous solution.

Leukopenia has been reported during paba therapy. Agranulocytosis might result.

#### *Supportive Therapy and Para-aminobenzoic Acid*

The clinical studies of Harrell and his co-workers<sup>2</sup> and of Ravenel<sup>3</sup> have emphasized that with the development of Rocky Mountain spotted fever, dehydration, loss of serum protein and blood chlorides, acidosis and in some cases anemia occur. The treatment according to Ravenel<sup>4</sup> is as follows: the fluid

expression to the psychical" and "each of the two achieves its aim only by reason of a *contact utile* between them"

And this liaison can rank as the final and supreme integration completing its individual. But the problem of *how* that liaison is effected remains unsolved, it remains where Aristotle left it more than 2000 years ago

As Fulton<sup>2</sup> notes "To the most profound student of the nervous system the world has yet known, the mind of man remains still unexplained"

Many will believe with Fulton that the problem is not quite where it was two thousand years ago, thanks to the researches of the former Waynflete Professor of Physiology at Oxford. Sherrington has at least pointed the road that will one day lead to an answer to this age-old question. Others,<sup>3-7</sup> moreover, took advantage of Sherrington's birthday to express similar sentiments

#### CONGRESS LOOKS AT HEALTH

It was perhaps inevitable that in anticipation of a national election there emerged a small avalanche of legislation related to matters that might be issues in the campaign

There seemed to be no profit for any political party in the forwarding of such major projects as the Wagner-Murray-Dingell Bill or the Taft Bill, both of which were killed. The National Science Foundation Bill (S 2385) finally failed of adoption, although in principle this seemed to be the proper approach toward solution of the part Washington should play in helping the earlier realization of actual and potential values made available by the several groups in the field of science

The medical parts of the program—for example, those relating to research and control in diseases of the heart and circulation—will be less well forwarded by such a bill as S 2215 (the National Heart Bill), and scientific advance will not be as

well integrated by it. This bill, introduced by Senators Bridges, Pepper, Ives and Murray, as specialized legislation aimed at meeting needs only in a single field, important as they are, was finally adopted with amendments

Many people believe that infantile paralysis has absorbed too large a proportion of public funds for the needs or accomplishments, when comparison is made with the much higher morbidity and mortality of circulatory diseases. Perhaps it is not surprising that some of the cardiologists who felt this disproportion keenly were strongly behind specialized legislation for their own interests, whereas other wise cardiologists, perhaps with larger perspective, preferred to take their chances with a much more comprehensive kind of legislation like the National Science Bill. Some there are who believe that there is no need for federal legislation in these matters. There seems, however, to be general agreement that all-over co-ordinated scientific investigation would accelerate the finding of needed truths that seem just beyond the horizon

Scientific research under governmental organization was performed so successfully in wartime that we may hope to see the thread picked up again. Compromise is necessary in legislation, but compromise with loss of larger obtainable values represents a shortsighted policy

#### KICKBACKS KICK BACK

BLINDED, no doubt, by the bright sunshine of the brilliant land in which they practice their art, an impressive number of the physicians of Los Angeles County seem unable to have read with understanding the Principles of Medical Ethics of the American Medical Association. Ironically, this visual incapacity has had to do with the receiving of rebates or "kickbacks" on eyeglass prescriptions from the local purveyors of these optical adjuncts

For eight years efforts from within the medical profession were of no avail in putting to an end this lucrative by-product of a professional activity otherwise not without honor. Eventually, however, the Los Angeles Better Business Bureau, aided by the *Reader's Digest* and the backing of the Los An-

## CORRESPONDENCE

## SUSPENSION OF REGISTRATIONS

To the Editor It has come to my attention that through a clerical oversight in this office, you were not notified that the registrations of several physicians were suspended because of their failure to comply with our statutory requirement concerning United States citizenship.

Under Chapter 415, Section 3, of the Acts of 1939, all physicians registered by the Board must satisfy the Board that they are American citizens. An attempt was made to communicate with such physicians whose applications indicated that they were born outside the United States. As a result of the information received, on July 12, 1946, the Board voted to suspend the registrations of the following physicians because they have stated they are not citizens of the United States or do not intend to become citizens.

Walter Bergwell	Lund, Sweden
John R. Corbett	Summerside, P. E. I.
Arthur G. Corea	Boston, Mass.
Derek Denny-Brown	Boston, Mass.
Robert H. Ellis	Ottawa, Ontario
Hubert Giovannetti	Sidney, Nova Scotia
Arthur M. Goulding	Toronto, Ontario
Marion Hook	Hastings, England
William M. Lynch	Sherbrooke, Quebec
Sidney H. McPherson	West Hartford, Conn.
Geraldine Oakley	Calgary, Alberta
Margaret Parks	St. John, New Brunswick
Elizabeth Ross	Meadowville, Nova Scotia
John R. Ross	Poughkeepsie, New York
Howard H. Smith	Charlottetown, P. E. I.
Edward V. Sullivan	Fairville, New Brunswick
Everett O. Thomas	St. Stephen, New Brunswick
Stephen B. Thorson	Winnipeg, Manitoba
Edmund Eugene Walker	Springfield, Mass.

## BOOK REVIEW

*Congenital Malformations of the Heart* By Helen B. Taussig, M.D. 4<sup>th</sup> ed., cloth, 618 pp., with 177 illustrations. New York: The Commonwealth Fund, 1947. \$10.00.

This volume has long been awaited by the pediatrician and the specialist in cardiovascular disease. Ten years have elapsed since Gross first successfully ligated a ductus arteriosus. This decade has witnessed the emergence of congenital heart disease from its obscurity as the academic diversion of the ultraspecialist to a position of importance in the consciousness of the practitioner and even of the layman. This evolution has been in large measure the result of a series of brilliant surgical procedures and the development of improved methods of study (notably angiography and cardiac catheterization). For the past twenty years Dr. Taussig has been intimately concerned with this progress, and she is responsible for the fundamental clinical observation upon which the now well-known Blalock-Taussig operation is based. This timely volume reflects the author's wide experience in this field.

The book is divided into four parts. The first deals with basic principles, methods of diagnosis and the physiology of the malformed heart. The second concerns malformations of the heart in which there is difficulty in supplying the body with adequate oxygenated blood. The third involves malformations compatible with life for many years, and the fourth is devoted to therapy.

The arrangement of the book is logical. The style is readable and direct, and frequent diagrams of the altered circulation are most helpful in elucidating the more complicated defects. The text is further strengthened by a summary at the end of each important discussion. Perhaps in some instances these summaries would have been more forceful

bad they been shorter. The illustrations are generous and effective.

This volume is destined to take its place beside the important studies of Maude Abbott as a standard reference for those concerned with this special field.

## BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

*Andreas Vesalius Bruxellensis. The bloodletting letter of 1539. An annotated translation and study of the evolution of Vesalius's scientific development.* By John B. de C. M. Saunders, F.R.C.S. (Ed.) and Charles D. O'Malley. 8<sup>th</sup> ed., cloth, 94 pp. New York: Henry Schuman, 1947. \$5.00. Limited to 500 copies.

It is noteworthy that this is the first published translation into English of a complete work of Vesalius. Professor Charles U. Clark, of Toronto, had previously made an unpublished translation of the venesection letter, which was made available to the authors, who checked it with their manuscript. The authors in their introduction trace the scientific development of Vesalius, placing the letter on venesection midway between his pure Galenic anatomy, as shown in his recension of Gunter's *Institutiones anatomicae* (1538) and his scientific treatise on anatomy, the *Fabrica* (1543). They point out that Vesalius not only was an anatomist but also was greatly interested in the whole field of medicine. The venesection problem is considered in all its aspects, beginning with the writings of Hippocrates, Galen and other classic writers and ending with the controversy of the contemporaries of Vesalius. The scholarly annotations to the introduction and the text are invaluable. The publishing is excellent in every way. The monograph should be in all medical-history collections.

*Private Enterprise or Government in Medicine.* By Louis H. Bauer, M.D. 8<sup>th</sup> ed., cloth, 201 pp. Springfield, Illinois: Charles C. Thomas, 1948. \$5.00.

Dr. Bauer, a trustee of the American Medical Association and currently president of the Medical Society of the State of New York, in this monograph presents a study of the proposed socialization of medicine by the federal Government and the counterproposals by the American Medical Association and the proponents of voluntary sickness insurance. The preliminary chapters discuss the state of medical care in the United States, the growth of Government in medicine and public health and foreign medical systems and their comparison with American systems. The following chapters consider the compulsory-sickness-insurance movement through 1944 and the legislation before Congress in 1945 to 1947. The various bills, including the Sheppard-Towner Act, the first Wagner bill of 1939, the Wagner-Murray-Dingell bill of 1943, the second bill of 1945 by the same group of senators, the third bill by the same group introduced in 1945 and providing for a national health program, the Fulbright-Taft bill of 1947 and the Taft-Smith-Ball-Donnell bill (S. 545) of 1947, are analyzed and discussed in relation to the problem of adequate medical care for the people of the United States. Also are considered and analyzed the voluntary insurance system and the ten-point plan of the American Medical Association. Included is the famous message to Congress of President Truman, dated November 19, 1945, requesting legislation for adoption of a national health program, and discussion of the work of the Committee on the Costs of Medical Care, the National Health Survey of 1935 and the National Health Conference of 1938. A chapter is devoted to the development of the voluntary insurance system in the United States. A bibliography of pertinent references is appended to the text. The book is well published in the characteristic good style of the publisher. It should be in all medical and general libraries and read by all physicians interested in the problem of the socialization of medicine.

and electrolyte balance should be restored to normal by means of intravenous injections of glucose in physiologic saline, lactate or Ringer's solution and should be maintained at a normal level by oral intake of fluid and added sodium chloride. Intravenous injections of electrolytes in solution in a patient whose serum protein is too low will serve only to produce more edema and possibly circulatory failure with pulmonary edema. Acidosis may be corrected by intravenous or subcutaneous injections of sixth molar solution of sodium lactate in appropriate dosage. The serum protein level of the blood depleted in the disease by starvation, vascular damage and liver failure should be restored to normal by intravenous injection of plasma and, in emergencies, serum albumin. This level should be maintained by plasma and a high-protein diet. If anemia develops blood should be given freely. Blood from patients convalescing from Rocky Mountain spotted fever is of no particular value. A high intake of vitamins should be furnished. Thiamin is given to help prevent shock. Ascorbic acid is given to obviate blood-vessel endothelial damage, and vitamins B complex and K for liver damage and to reduce increased prothrombin time. Depending on the size of the patient 0.5 to 1 gm of para-aminobenzoic acid per pound of body weight per day is given. Small children receive 1 gm per pound, very large children, half that amount, and the intermediate, about 0.75 gm. This is partially buffered with 10 cc of a 5 per cent solution of sodium bicarbonate per gram to prevent acidosis and nausea, and is given at two-hour intervals. The blood level of the drug should be estimated each day, in each case the same length of time after a dose of the drug. A level of 30 to 60 mg per 100 cc is desirable, 60 to 80 mg may be hazardous. Administration is continued four or five days after the temperature has reached normal.

The toxic effects of para-aminobenzoic acid to be watched for are acidosis, leukopenia, abdominal distention and delirium. If the white-cell count falls to 3000, the paba should be discontinued. Tympanites and delirium occur fairly frequently but are probably of little importance.

The complications of Rocky Mountain spotted fever are congestive heart failure (for which oxygen and digitalis in full dosage are helpful), pneumonia (usually lobar and rickettsial, ordinarily not helped by penicillin), encephalitis and thrombophlebitis. The heart failure is usually reversible, and when recovery occurs it is complete. It is possible but extremely difficult to treat these patients without laboratory control. Frequent determinations of the carbon dioxide combining power, serum protein and para-aminobenzoic acid levels of the blood are virtually a necessity, and determinations of the nonprotein nitrogen and chloride blood levels and prothrombin time may be a valuable aid.

Rocky Mountain spotted fever causes extreme vascular damage. Intravenous fluids used in therapy should be given cautiously to guard against unfavorable reactions.

### Serum

Hyperimmune rabbit serum has been shown to have a definitely protective and therapeutic effect in experimental animals if used early during the infection. It has been employed in numerous human beings and appears to be beneficial, particularly if administered before or shortly after the rash appears. It is available commercially from Lederle and Sharp and Dohme. The recommended dose is 1 cc per kilogram of body weight. Directions for testing the patient's sensitivity to rabbit protein and dosage accompany the antiserum.

Neoarsphenamine in metaphen solution, penicillin and sulfonamide drugs have been tried with no evidence of any beneficial results.

### MISCELLANY

#### DR DEWITT C. ROMAINE FELLOWSHIP

Columbia University College of Physicians and Surgeons has received a bequest, amounting to approximately \$140,000, from the estate of the late C. Evaretta Romaine, it was recently announced. The fund, which will be set up as the Dr. DeWitt C. Romaine Fellowship, will be used to investigate diseases of the blood system and other medical problems.

#### VETERANS ADMINISTRATION

Dr. Augustus Thorndike, of Boston, has been appointed director of Veterans Administration Prosthetic and Sensory Aids Service. Dr. Thorndike, who graduated from Harvard Medical School in 1921 and served overseas with the 103rd General Hospital, developed and directed the Army's reconditioning program for disabled soldiers. He was awarded the Legion of Merit for this work.

#### WHO PROGRAM

The Interim Commission of the World Health Organization, which now consists of 43 nations — 33 UN members and 10 nonmembers — has declared its program for 1949. It is proposed to concentrate on four international problems — malaria, maternal and child health, tuberculosis and venereal disease. Forty-four other medical and related fields will also be included in the Commission's activities. Work on an international pharmacopoeia is also progressing under the aegis of the Expert Committee on the Unification of Pharmacopoeias.

## NOTICES

### BIOLOGY CONFERENCE, BROOKHAVEN NATIONAL LABORATORY

The Biology Department of Brookhaven National Laboratory announces a conference to be held at Brookhaven from July 26-30 on the subject, "Biologic Applications of Nuclear Physics." The program will include sessions on health physics, isotope techniques and applications of radiocarbon, radioiron and radiophosphorus. The last three days will be devoted to a symposium on radioiodine. Reservations for attendance at the conference will be filled in the order in which they are received.

Applications for registration and inquiries should be addressed to Miss Ellen Matteson, Brookhaven National Laboratory, Upton, New York (telephone, Patchogue 2600, Extension 114).

BOSTON 15, MASS

*Endocrine Therapy in General Practice* By Elmer L. Sevringhaus, M.D., director, Endocrine and Nutritional Clinics, Gouverneur Hospital, New York City. Sixth edition. 8°, cloth, 264 pp., with 49 illustrations. Chicago: The Year Book Publishers, Incorporated, 1948. \$4.00.

This book, first published in 1938, has passed through six editions and seven printings, speaking well for its soundness and popularity. This new edition has been carefully revised to keep it abreast of current knowledge in its field. Although no major changes have been made in the text, about a third of the pages have been altered. The printing is well done with a good, large type that is easy to read. The book is recommended for all medical libraries and should prove valuable to physicians interested in the subject.

*Illustrative Electrocardiography* By Julius Burstein, M.D., visiting electrocardiographer and chief of the Cardiac Clinic, Morrisania City Hospital, New York City, and associate cardiologist and chief of the Cardiac Clinic, Jewish Memorial Hospital, New York City, and Nathan Bloom, M.D., associate professor of medicine and chief of the Department of Electrocardiography, Medical College of Virginia, Richmond. Third edition. 8°, cloth, 309 pp., with 99 plates. New York: D. Appleton-Century Company, Incorporated, 1948. \$6.00.

This work, first published in 1935, has been thoroughly revised to bring it up to date with the significant advances in its field. All but two of the ninety-nine plates are new. A chapter on radiology of the heart by Dr. Philip Slater has been added. A good index concludes the volume. The publishing is excellent.

*The Case of Rudolf Hess: A problem of diagnosis and forensic psychiatry* By the following psychiatrists in the Services who have been concerned with him from 1941 to 1946: Henry V. Dicks, M.D., J. Gibson Graham, M.D., M. K. Johnston, M.D., D. Ellis Jones, M.D., Douglas McG. Kelley, M.D., N. R. Phillips, M.D., and G. M. Gilbert, Ph.D. Edited by J. R. Rees, M.D. 8°, cloth, 224 pp. New York: W. W. Norton and Company, Incorporated. \$3.00.

This monograph constitutes a case history of Rudolf Hess by the eight British and American psychiatrists who were concerned with him from 1941 to 1946. The case is studied from the time Hess parachuted into England, in May, 1941, until his appearance before the Nuremberg tribunal in 1946. The last chapter is a general review of the case, and the considered opinion of the psychiatrists favors a diagnosis of schizophrenia of a paranoid type. An appendix contains the documents presented to the Nuremberg court. The book is well published and reasonably priced. This unusual case history should be in all psychiatric collections.

*An Introduction to Gastro-Enterology: A clinical study of the structure and functions of the human alimentary tube* By James D. Lickley, M.D. 12°, cloth, 143 pp., with 21 illustrations. Baltimore: The Williams and Wilkins Company, 1947. \$3.00.

This small manual was written for senior medical students and beginning practitioners in the field of gastroenterology. The text is well written and well organized, and the volume well published. The printing was done in Great Britain.

*A Manual of Clinical Therapeutics: A guide for students and practitioners* By Windsor C. Cutting, M.D., professor of therapeutics, Stanford University School of Medicine, San Francisco, California. Second edition. 12°, cloth, 712 pp., with 30 illustrations. Philadelphia: W. B. Saunders Company, 1948. \$5.00.

This manual, first published in 1934, has been revised to bring it up to date. Material has been added, especially on the antibiotics, antimalarials, antihistamines, antithyroid drugs, anticonvulsants, folic acid and plasma fractions. Exact dosages for children have been inserted in an appendix. Diet lists and a number of illustrations have been added to the text. The various appendices of special procedures, diet therapy, symptoms and treatment of poisoning, diet lists, metric and English equivalents, tables and charts for weight, height and age, prescription abbreviations and for weight, height and age, prescription abbreviations and other data, clinical and physiologic data and a list of prescrip-

tions, drugs and doses add much to the value of the work. Especially valuable is the list of therapeutic agents and dosages. The volume is well published and should prove useful as a ready reference source to all medical librarians and physicians.

*Advances in Military Medicine Made by American Inventors working under the sponsorship of The Committee on Medical Research* Edited by E. C. Andrus, D. W. Brook, G. A. Carden, Jr., C. S. Keefer, J. S. Lockwood, J. T. Wearn and M. C. Winternitz. Associate editor: Tuckerman Day. With a foreword by Alfred N. Richards. In two volumes. 8°, cloth. Volume I, 472 pp., and 62 illustrations. Volume II, 900 pp., and 94 illustrations. Science in World War II. Office of Scientific Research and Development. Boston: Little, Brown and Company (An Atlantic Monthly Press Book), 1948. \$12.50 for the two volumes.

The work describes the activities of the Committee for Medical Research of the Office of Scientific Research and Development and constitutes a history of medical progress during World War II. The Committee was established in June, 1941, by presidential order, and nearly 1700 physicians and 3800 scientifically trained research workers were associated with the Committee. Its staff was divided into six sections: medicine, surgery, physiology, chemistry, aviation medicine and malaria. The material in the two-volume set is arranged in the same divisions, with supplementary chapters on penicillin and sensory devices. In the section on chemistry there are a number of papers on chemical-warfare agents and antipest agents. In physiology are discussed shock, plasma, blood substitutes and whole blood, problems of nutrition, water disinfection, acclimatization to heat and cold and protective clothing. In medicine the principal topics are infections and venereal and tropical diseases. Aviation medicine includes the study of crash injuries, effects of acceleration, visual problems, motion sickness, anoxia and altitude-decompression sickness. Surgery includes papers on infection, wound healing, orthopedics, gas gangrene, burns, peripheral nerve lesions, concussion, frostbite and trenchfoot and surgical plastics and hemostatics. Malaria is considered in five chapters. A good index concludes the text, which is paginated continuously through the two volumes. There is a large bibliography of the writings of persons working on contracts with the Committee and a list of the contracts. The publishing is good in every way. The work is recommended for all medical and general libraries.

*Experimental Air-Borne Infection* By Theodor Rosebury. With the co-authorship and assistance of the staff of the Laboratories of Camp Detrick, Maryland. 8°, cloth, 222 pp., with 75 tables. Baltimore: The Williams and Wilkins Company, 1947. \$4.00. *Microbiological Monographs*. Official Publication of The Society of American Bacteriologists.

This report presents the major results of a co-operative wartime project carried out at Camp Detrick, beginning in December, 1943, and ending after the cessation of World War II. A special blood chamber was constructed and after safety tests had been made and found satisfactory, work with infective agents was begun March 21, 1945, and continued until the project was terminated. The text is divided into five sections, the first four considering the history of the subject, equipments and methods, the selection of an atomizer and basic data. Section five discusses the stability and infectivity of a group of special bacteria and viruses. A summary concludes the text. The material is well arranged, and the text well written. The volume is well published in every way. It forms the first volume of a new series of microbiologic monographs and is an official publication of the Society of American Bacteriologists. It is recommended for all medical libraries and public-health collections.

*Fundacion Lucas Sierra: Hospital de Viña del Mar. Journales Clinicas de Ferano*, 1947. 4°, paper, 304 pp., with 46 illustrations. Viña del Mar, Chile: Fundacion Lucas Sierra, 1947.

This volume constitutes the proceedings of a three-day clinical conference held at Verano, Chile. Papers were read by specialists on special anesthesia, salivary lithiasis, diabetes, cholecystitis, allergy, diseases of the biliary tract, leukemia, surgery of the thorax, heart and hypertension, the biliary tract, and hospital organization. The volume is well published and should be in all large medical libraries.

## THE VALUE OF ANTIBIOTICS IN DIABETIC SURGERY\*

M J KUFFEL, MD † L N IRVIN, MD † D H HOOKER, MD † AND D P FOSTER, MD §

DETROIT, MICHIGAN

IF A diabetic patient must submit to major surgery, what is his prognosis? Or if a person has inherited the recessive genes of diabetes where should his interest be directed to prevent a frank diabetic state and the inevitable associated surgery? According to Root,<sup>1</sup> practically every diabetic patient at some time in his life is operated on and the prognosis is materially affected by the efficiency of diabetic control during the years preceding the emergency.

The reduction of the mortality in diabetic surgery over the years has been striking. Before the discovery of insulin in 1922 the surgical mortality stood at the appalling figure of 40 to 80 per cent.<sup>2</sup> In contrast, Joslin<sup>3</sup> reports a mortality of 11.5 per cent at the New England Deaconess Hospital for the period 1923 to August 1, 1926. From 1923 to 1941 the rate at the same institution was 7.3 per cent. Finally, from 1942 to January, 1946 the mortality dipped to a new low of 2.2 per cent. Joslin believes that this last improvement has been due in a large measure to the use of antibiotics. It is the purpose of this paper to draw a comparison between the management and surgical results in diabetes before and after the introduction of penicillin.

It is well known that the most prominent and universal pathologic change in diabetes is arteriosclerosis. Root et al.<sup>4</sup> have shown that coronary occlusion occurs three to eight times more frequently in diabetic patients over fifty years of age than in nondiabetic persons. McLaughlin<sup>5</sup> has stated that calcification in the peripheral vessels is demonstrable in 91 per cent of all patients who have had diabetes ten years and that pulsations in the arteries of the lower extremities tend to disappear ten to twenty years earlier than in nondiabetic persons. Root<sup>1</sup> claims that some degree of vascular nephritis can be demonstrated in almost all diabetic patients beyond fifty years of age. This generalized arteriosclerotic state in addition to producing grave circulatory changes may contribute to frequent and dan-

gerous skin infections. Boyd<sup>6</sup> considers the presence of large amounts of sugar in the tissues together with the hypemia resulting from faulty metabolism to be an important factor. We believe that hyperglycemia alone does not necessarily promote infection provided sufficient amounts of sugar are being metabolized.

The pathologic changes in diabetic tissue are the result of a vicious circle, which involves faulty circulation and anoxia and also tissue degeneration, often complicated by infection, fever and local edema. General toxemia leads to a diminished tolerance for carbohydrates. One method of attacking this circle is by decreasing or eradicating the infection. This can be accomplished more often and more quickly with antibiotics.

The recuperative power of the pancreas is normally very great when infection is controlled. Eisele<sup>7</sup> reported a diabetic patient with a diseased gall bladder requiring 1000 units per day preoperatively, who became insulin resistant. Two years after cholecystectomy the patient was asymptomatic and required no insulin.

### TREATMENT BEFORE AND AFTER OPERATION

The diabetic patients operated on at the Henry Ford Hospital are generally prepared as follows. On the day before the operation blood sugar, carbon dioxide combining power and blood chloride are taken. If these are within normal range, the diet is withheld on the morning of surgery and in its place 300 cc. of 20 per cent glucose is given intravenously with 10 units of regular insulin. Immediately on return from the operating room the patient is given another 300 cc. of 20 per cent glucose intravenously with 10 units of regular insulin followed by a clivsis of 1000 cc. of physiologic saline solution. The blood pressure is taken every two hours (for a period dependent on the condition of the patient) and 500 cc. of whole blood or plasma is given if the systolic pressure drops below 100. Excessive loss of fluids by profuse sweating or vomiting or drainage is replaced by additional clivses.

Food by mouth is offered on the evening of the first postoperative day in the form of fruit juices.

# BACKGROUND

The use of cow's milk, water and carbohydrate mixtures represents the one system of

infant feeding that consistently, for over three decades, has received universal pediatric

recognition. No carbohydrate employed in this system of infant feeding enjoys so rich and enduring a background of authoritative clinical experience as Dextri Maltose

The types of anesthetics and their combinations are illustrated in Table 6. The selection depends on the type of case, and the judgment and experience of the surgeon. Joslin<sup>9</sup> believes that with the aid of insulin, any type of anesthetic may be used. All observers agree that some have certain advantages over others. Root,<sup>1</sup> in studies using carbon dioxide levels as an indicator, has shown that the anesthetics of choice in order of value are spinal, ethylene, nitrous oxide and ether, and cyclopropane, the last being excellent for patients presenting cardiac complications. Other writers give different preferences. McKim and Fowler<sup>10</sup> favor cyclopropane. Where it can be used, all agree that local anesthesia is by far the safest. Hale and Tovell<sup>11</sup> point

blood sugar values are increased. Avertin is to be condemned because it is more toxic to the liver cells and the liver is slower in recovering than with other anesthetics.<sup>16</sup> Anoxia, which is a side effect of any general anesthetic and is of grave concern to the

the current use of penicillin, septicemia represented the greatest single cause of death. There were no deaths from septicemia among the more recent cases. This is consistent with Joslin's<sup>3</sup> statement that

TABLE 7 Causes of Death

"deaths from septicemia have ceased, thanks to penicillin."

We believe that the marked improvement in mortality in recent years is due for the most part to the

out the inadvisability of its use in areas deficient in circulation. There is much to be said of the advantages of refrigeration anesthesia. Many commonly used agents have been shown to have extremely undesirable and dangerous side effects. In animal experiments with ether, Bloor<sup>12</sup> has reported an increase in blood fat from 40 to 100 per cent, the rate of rise being greatest during the first hour. Brown and Long,<sup>13</sup> after two and a half hours' administration of ether to cats, found an 87 per cent reduction of glycogen in the cardiac musculature. It is well known, as cited by Wilcox and Tovell,<sup>14</sup> that even in normal subjects ether produces an acidotic condition proved by recovery of acetone bodies in the urine. Foster<sup>15</sup> believes that ether probably interferes with the utilization of carbohydrate since

gingerale, milk and buttermilk as tolerated, or up to 6 ounces every two hours. In addition, sufficient 5 per cent glucose is given intravenously to total an intake of 100 gm of carbohydrate per twenty-four hours. During that time, the urine is examined for sugar every two hours. If the reaction is ++ or more, 10 units of regular insulin is given. From this point the oral consumption of food is gradually increased as tolerated until the patient is again on his regular diabetic diet. During this convalescent period the urine is tested four times daily (before meals and at bedtime), and regular insulin given as described above. From these values together with a daily fasting blood sugar determination, the proper dosage of protamine zinc insulin is calculated. In certain cases it may be necessary to use supplementary regular insulin before meals and at bedtime.

The diabetic patient in acidosis, requiring surgery, presents a more complex problem. Except in cases of dire necessity, no patient should be subjected to operation whose carbon dioxide combining power is below 30 vol per cent or with a blood sugar above 350 mg per 100 cc. Much can be accomplished to correct these conditions within the first four to six hours after admission. An outline of the treatment of acidosis is tedious and detailed and seems to have no place in this report. For a comprehensive outline of our views of that subject, the reader is referred to the work of Foster et al.<sup>8</sup>

### DISCUSSION

The series of cases herein reported consists of two groups, each representing a different era of management. The first group includes 215 diabetic patients operated upon prior to 1940—that is, be-

TABLE 1 Sex Incidence

PERIOD	MALE PATIENTS		FEMALE PATIENTS	
	NO	PER CENTAGE	NO	PER CENTAGE
Before 1940	85	39.5	130	60.5

fore penicillin was available. The second comprises 111 operations performed between January 1, 1945, and January 1, 1947, selected from 825 diabetic cases excluding fractures, dental procedures and all pediatric surgery, the antibiotics, particularly penicillin, were used freely with telling effect in this group.

The sex incidence shows a 7 per cent increase in surgical intervention for male patients in the second group (Table 1). Although the variance is not great, it suggests a tendency toward self-neglect during the war years.

The age incidence in both groups indicates that approximately 90 per cent of the patients were over

forty years of age (Table 2). This figure obviously illustrates the importance of adequate management of uncomplicated diabetes after middle age. Our results seem to parallel those of others in that the

TABLE 2 Age Incidence

AGE	PATIENTS IN FIRST GROUP		PATIENTS IN SECOND GROUP		ALL PATIENTS	
	NO	PER CENTAGE	NO	PER CENTAGE	NO	PER CENTAGE
50+						
0-9	3	1.4	—	—	3	0.91
10-19	4	1.9	2	1.8	6	1.69

70-79	23	10.7	14	12.6	37	11.35
80-89	4	1.9	1	0.9	5	1.52

greatest incidence of diabetic surgery was in the fifth decade of life.

On discharge approximately 73 per cent of cases in the second group showed a blood sugar level of less than 150 mg per 100 cc (Table 3). Three cases exhibited 250 mg per 100 cc or more. This excellent control can be attributed in a large measure to the efficacy of protamine-zinc insulin and penicillin, particularly in view of the fact that many of these patients were discharged prior to the complete healing of their wounds.

An analysis of the diet indicates a trend toward increasing the carbohydrate allowance (Table 4). This is also true, in a lesser degree, of the protein prescribed, whereas the fat intake remains fairly constant.

The miscellaneous operations in Table 5 include simple procedures such as removal of cysts and wens, venous ligation, skin grafts and the extraction of foreign bodies. Amputations and skin infections constituted approximately a third of the cases. These conditions are given careful consideration because they are, in a large degree, preventable through early education and proper management of

\*In the patients who died, the last blood sugar prior to death is recorded.

the patient. The patients in the second group showed a 50 per cent reduction in skin infection requiring surgery, again owing, we believe, to the use of penicillin.

It is rather striking that not a single case of glomerulonephritis is reported by the investigators<sup>11, 12</sup> mentioned above.

So far as animal experimentation is concerned, Bersh and Grollman,<sup>8</sup> Marshall and Davis,<sup>9</sup> Swingle<sup>10</sup> and Harrison and Darrow<sup>11</sup> found no significant diffuse renal damage in their adrenalectomized animals. On the other hand, Marine,<sup>12</sup> MacMahon and Zwemer,<sup>13</sup> Simpson and Korenhevsky,<sup>14</sup> Banting and Gairns<sup>15</sup> and Hartman et al.<sup>16</sup> observed rather extensive renal disease in their adrenalectomized animals.

Thorn, Koepf and Clinton,<sup>17</sup> in 1944, described 2 cases of renal failure with a syndrome simulating adrenocortical insufficiency. They ascribed this syndrome to the loss of sodium and chloride secondary to renal disease rather than disease of the adrenal cortex. They demonstrated that in these cases relief was not afforded by treatment with adrenocortical substances but was attained by treatment with sodium chloride. The authors implied that the renal tubule is the end-organ for the adrenocortical hormones concerned with the balance of sodium and potassium in the plasma and the urine. To maintain a normal electrolyte balance the organism requires a normally functioning adrenal cortex as well as an intact renal tubule.

The following case is presented as one in which the disturbed physiology leading to death resulted from the worst possible combination—that of a diseased adrenal cortex and a diseased end-organ. It is possible that these two organs, the adrenal cortex and the kidney, suffered damage from a common etiologic agent. Since the renal lesion in this case was of a rather specific character, it is more probable that this was a case of two major coexistent diseases, each a result of a different etiologic mechanism.

### CASE REPORT

A. Y., a 55-year-old married man, was admitted to the hospital on April 10, 1947. He complained of generalized itching of 9 weeks' duration. A rash, which had started on the thighs, had spread rapidly to the trunk, neck, arms, buttocks and lower legs. The lesions had become vesiculated and weeping over both lower legs. The patient had noticed marked darkening of the skin over all areas involved by the rash.

His occupation had brought him in daily contact with raw camel and alpaca wool.

Seven years before admission, he had begun to suffer from episodes of diarrhea occurring off and on at irregular intervals. One of those episodes was so severe that it lasted "nearly a year." No cause for this condition was found at the time. The attacks of diarrhea were interspersed with attacks of constipation of such severity that it necessitated frequent recourse to "laxatives." The patient had noticed a recent increase in nervousness and fatigability.

For 3½ years previous to admission, he suffered from mild "bronchial asthma," for which he was treated by desensitization to kapok and "dusts."

There was a history of nocturia and albuminuria of at least 4 years' duration, and about 4 years before admission a physician had made a diagnosis of "chronic nephritis." X-ray study of the chest in 1942 had shown "old calcified tuberculosis," inactive. There were no significant data in the family and past histories, except that the patient's father had died of pulmonary tuberculosis at the age of 57.

Physical examination revealed a thin, apprehensive man in marked discomfort from a generalized itching rash. There was a mild seborrheic dermatitis of the scalp and an erythematous, papular excoriated rash over the thighs, buttocks, legs, trunk, neck and upper arms. Over the lower legs this had become vesiculated, weeping and impetiginous. In all areas involved by the rash, a blotchy, tan pigmentation of the skin had become confluent over the genitalia, thighs, neck and lower legs. There were large, tender femoral and inguinal lymph nodes bilaterally. There were a few small patches of brownish pigmentation on the hard palate and a few small irregular spots of blue-brown pigmentation of the buccal mucosa and the soft palate. Breath sounds were of the asthmatic type, and there were numerous musical expiratory rales throughout the chest. The heart was not enlarged and no murmurs were heard. The abdomen was essentially normal. The prostate was slightly enlarged, smooth and firm.

The blood pressure was 150/100, and the pulse 100. Examination of the blood disclosed a hemoglobin of 10.5 gm per 100 cc (photoelectric-cell technic), a white-cell count of 12,000 and a blood chloride (as sodium chloride) of 411.

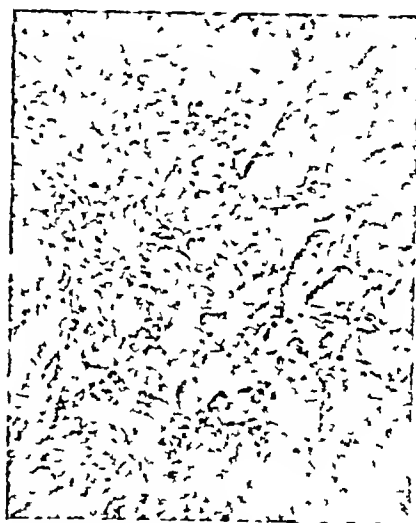

FIGURE 1. Hematoxylin and Eosin Stain of Suprarenal Glands, Showing Nodular Acute Accumulations of Cortical Cells, Fibrosis and Lymphocytic Infiltrations (x150).

mg and a blood urea nitrogen of 27 mg per 100 cc. Four morning urine specimens showed a maximum specific gravity of 1.012, two specimens contained a trace of albumin and a moderate number of finely granular casts. A film of the chest demonstrated healed apical tuberculosis on the left and a heart of normal size.

The patient was treated symptomatically for his dermatitis, receiving moist compresses to his lower legs, and calamine lotion to the rest of his body. During the first 10 hospital days he remained afebrile, ate well and felt relatively comfortable. There was some improvement of his dermatitis and marked relief from the pruritus. The pigmentation remained unchanged. On the 9th hospital day, repeated checking showed a blood pressure of 145/95 to 150/100.

On the 11th hospital day the patient became drowsy, but stated that otherwise he felt fine. His blood pressure dropped to 70/45, the pulse rose to 120, and his temperature to 105°F by rectum. He vomited once during the day but thereafter took some fluids and soft food by mouth without nausea, vomiting or diarrhea. The white-cell count was 17,400, with 50 per cent neutrophils, a blood culture showed no growth, the nonprotein nitrogen was 75 mg, the creatinine 4.5 mg, the chloride (as sodium chloride) 444 mg, and the fasting blood sugar 114 mg per 100 cc.

Addisonian crisis was suspected. Despite vigorous treatment with physiologic saline solution, glucose and adrenocortical hormones, the patient became progressively worse and died on the twelfth hospital day.

use of penicillin, but credit must also be given to the better understanding of the management of his case by the diabetic patient. In the 111 cases in the second group 52 per cent of patients were given penicillin. The dosage ranged from 100,000 to 400,000 units per day and covered a time range from two to forty-two days. The maximum total dosage used in a single case was 7,300,000 units.

### SUMMARY AND CONCLUSIONS

A survey of 326 cases of diabetic surgery is presented, one group, of 215 patients, operated on prior to 1940 without benefit of penicillin and the other, comprising 111 cases, treated surgically between January 1, 1945, and January 1, 1947, with the liberal use of penicillin. The results are compared.

Approximately 90 per cent of patients came to surgery after the age of forty years. There was moderate variation in the sex incidence.

The practice of increased carbohydrate and protein allowance is substantiated.

A comparison of various anesthetics is made, the use of local anesthesia being preferable when possible. The dangers of anoxia are stressed.

A reduction in mortality from 10.7 to 4.5 per cent has been obtained. The use of penicillin in diabetes has removed septicemia as a cause of death and has become a major contribution in the management of diabetic surgery.

The diabetic patient facing surgery has, in recent years, entered an era promising much greater chances not only of survival but also of rehabilitation. Medical and surgical teamwork cannot be overemphasized. Penicillin has proved to be a formidable weapon.

## ADDISON'S DISEASE COMPLICATED BY CHRONIC GLOMERULONEPHRITIS\*

LOUIS RAVREBY, M.D.,† AND WILBUR H. SAWYER, M.D.‡

IN THE classic description of the disease that bears his name, Addison presented no significant clinical evidence of renal disease in any of the 11 cases he reported. Of those cases, all of which were autopsied, only one is reported to have been diffusely pathologic. He describes the kidneys of this case as "contracted and granular."<sup>1</sup>

### REVIEW OF THE RECENT LITERATURE

Regarding the effect of adrenocortical insufficiency on renal function, it is fair to state that very little of anything happens to renal function in the intercritical phases of Addison's disease. On the other hand, nearly all investigators find rather marked renal dysfunction during crisis, characterized chiefly by an elevated blood urea, nonprotein nitrogen and hyperproteinemia. This is attributed to the dehydration, hypotension, reduced blood volume and shock accompanying Addisonian crisis.<sup>1-4</sup>

This picture is reversed by treatment with salt and desoxycorticosterone acetate.<sup>1-3</sup> Soffer<sup>1</sup> regards this dysfunction as nonspecific and as similar to the renal dysfunction resulting from dehydration and shock from any cause.

The question of whether or not adrenocortical insufficiency results in any specific diffuse morphologic lesion in the kidney has not been satisfactorily answered. On the basis of human patients at autopsy, no renal lesion was found by at least two groups of investigators.<sup>4, 5</sup>

Rowntree and Snell<sup>1</sup> found cases of severe renal disease in about a third of their 31 autopsied cases, and only 1 with hypertension.

Of 566 cases selected from the literature, Guttman<sup>6</sup> observed anatomic changes in the kidney sufficient to render a diagnosis in only 10 per cent. The nature of the lesion in the involved kidneys is not described adequately enough to make any positive statement.

Only one author, Barker,<sup>7</sup> reported significant renal disease in 11 of a total of 28 cases of Addison's disease.

It is rather striking that not a single case of glomerulonephritis is reported by the investigators<sup>1, 4-7</sup> mentioned above.

So far as animal experimentation is concerned, Gersh and Grollman,<sup>8</sup> Marshall and Davis,<sup>9</sup> Swingle<sup>10</sup> and Harrison and Darrow<sup>11</sup> found no significant diffuse renal damage in their adrenalectomized animals. On the other hand, Marine,<sup>12</sup> MacMahon and Zwemer,<sup>13</sup> Simpson and Korenchevsky,<sup>14</sup> Banting and Cairns<sup>15</sup> and Hartman et al<sup>16</sup> observed rather extensive renal disease in their adrenalectomized animals.

Thorn, Koepf and Clinton,<sup>17</sup> in 1944, described 2 cases of renal failure with a syndrome simulating adrenocortical insufficiency. They ascribed this syndrome to the loss of sodium and chloride secondary to renal disease rather than disease of the adrenal cortex. They demonstrated that in these cases relief was not afforded by treatment with adrenocortical substances but was attained by treatment with sodium chloride. The authors implied that the renal tubule is the end-organ for the adrenocortical hormones concerned with the balance of sodium and potassium in the plasma and the urine. To maintain a normal electrolyte balance the organism requires a normally functioning adrenal cortex as well as an intact renal tubule.

The following case is presented as one in which the disturbed physiology leading to death resulted from the worst possible combination—that of a diseased adrenal cortex and a diseased end-organ. It is possible that these two organs, the adrenal cortex and the kidney, suffered damage from a common etiologic agent. Since the renal lesion in this case was of a rather specific character, it is more probable that this was a case of two major coexistent diseases, each a result of a different etiologic mechanism.

### CASE REPORT

A. Y., a 55-year-old married man, was admitted to the hospital on April 10, 1947. He complained of generalized itching of 9 weeks' duration. A rash, which had started on the thighs, had spread rapidly to the trunk, neck, arms, buttocks and lower legs. The lesions had become vesiculated and weeping over both lower legs. The patient had noticed marked darkening of the skin over all areas involved by the rash.

His occupation had brought him in daily contact with raw camel and alpaca wool.

Seven years before admission, he had begun to suffer from episodes of diarrhea occurring off and on at irregular intervals. One of those episodes was so severe that it lasted "nearly a year." No cause for this condition was found at the time. The attacks of diarrhea were interspersed with attacks of constipation of such severity that it necessitated frequent recourse to "laxatives." The patient had noticed a recent increase in nervousness and fatigability.

For 3½ years previous to admission, he suffered from mild "bronchial asthma," for which he was treated by desensitization to kapok and "dusts."

There was a history of nocturia and albuminuria of at least 4 years' duration, and about 4 years before admission a physician had made a diagnosis of "chronic nephritis." X-ray study of the chest in 1942 had shown "old calcified tuberculosis," inactive. There were no significant data in the family and past histories, except that the patient's father had died of pulmonary tuberculosis at the age of 37.

Physical examination revealed a thin, apprehensive man in marked discomfort from a generalized itching rash. There was a mild seborrheic dermatitis of the scalp and an erythematous, papular excoriated rash over the thighs, buttocks, legs, trunk, neck and upper arms. Over the lower legs this had become vesiculated, weeping and impetiginous. In all areas involved by the rash, a blotchy, tan pigmentation of the skin had become confluent over the genitalia, thighs, neck and lower legs. There were large, tender femoral and inguinal lymph nodes bilaterally. There were a few small patches of brownish pigmentation on the hard palate and a few small irregular spots of blue-brown pigmentation of the buccal mucosa and the soft palate. Breath sounds were of the asthmatic type, and there were numerous musical expiratory rales throughout the chest. The heart was not enlarged and no murmurs were heard. The abdomen was essentially normal. The prostate was slightly enlarged, smooth and firm.

The blood pressure was 150/100, and the pulse 100. Examination of the blood disclosed a hemoglobin of 10.5 gm per 100 cc (photoelectric-cell technic), a white-cell count of 12,000 and a blood chloride (as sodium chloride) of 411.

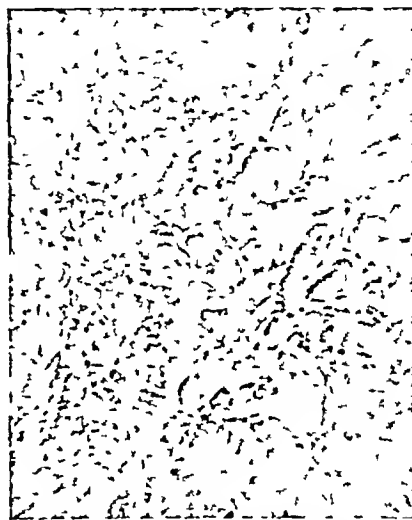

FIGURE 1 Hematoxylin and Eosin Stain of Suprarenal Glands, Showing Nodular Acute Accumulations of Cortical Cells, Fibrosis and Lymphocytic Infiltrations (x150)

mg and a blood urea nitrogen of 27 mg per 100 cc. Four morning urine specimens showed a maximum specific gravity of 1.012, two specimens contained a trace of albumin and a moderate number of finely granular casts. A film of the chest demonstrated healed apical tuberculosis on the left and a heart of normal size.

The patient was treated symptomatically for his dermatitis, receiving moist compresses to his lower legs, and calamine lotion to the rest of his body. During the first 10 hospital days he remained afebrile, ate well and felt relatively comfortable. There was some improvement of his dermatitis and marked relief from the pruritus. The pigmentation remained unchanged. On the 9th hospital day, repeated checking showed a blood pressure of 145/95 to 150/100.

On the 11th hospital day the patient became drowsy, but stated that otherwise he felt fine. His blood pressure dropped to 70/45, the pulse rose to 120, and his temperature to 105°F by rectum. He vomited once during the day but thereafter took some fluids and soft food by mouth without nausea, vomiting or diarrhea. The white-cell count was 17,400, with 50 per cent neutrophils, a blood culture showed no growth, the nonprotein nitrogen was 75 mg, the creatinine 4.5 mg, the chloride (as sodium chloride) 444 mg, and the fasting blood sugar 114 mg per 100 cc.

Addisonian crisis was suspected. Despite vigorous treatment with physiologic saline solution, glucose and adrenocortical hormones, the patient became progressively worse and died on the twelfth hospital day.

At autopsy\* the skin of the face, chest, abdomen and extremities was tannish brown. The anterior aspects of the lower extremities showed the skin to be scaly and desquamating. The serous cavities were not remarkable.

The heart weighed 250 gm. Except for brown atrophy of the myocardium, a thickening fibrosis and retraction of the mitral leaflets there were no gross abnormalities. The chordae tendineae were thickened, fused and shortened.

The lungs showed early acute bronchopneumonia at the bases of the lower lobes, and firm bilateral apical scars were present. The tracheobronchial lymph nodes were calcified.

The liver and gall bladder and extrahepatic bile ducts revealed no gross abnormalities. The spleen was not remarkable.

The right suprarenal gland measured 1 by 0.1 cm and weighed 1.2 gm. It was extremely soft in consistence, and the cortex was determined with difficulty. It was absent in some areas and when present was thin and tan. The medulla was a deep purple gray. The left suprarenal gland measured 1.2

increased in amount, and there were infiltrations of lymphoid cells. The small arteries and arterioles showed slight arteriosclerosis (Fig 2).

The pathological diagnoses were idiopathic cytotoxic atrophy of the suprarenal glands, chronic glomerulonephritis, mitral stenosis and insufficiency, healed apical tuberculosis and healed calcified tuberculosis of the mediastinal lymph nodes, brown atrophy of the myocardium, and bilateral, basal, acute bronchopneumonia.

## DISCUSSION

The combination of chronic glomerulonephritis and adrenal insufficiency is not common. In this case, it made the diagnosis of Addison's disease uncertain until crisis, as manifested by collapse, hypotension, hyperthermia and death, occurred. The addition of a severe contact dermatitis served further to obscure the underlying adrenal disease.

Asthenia, fatigue and nervousness had been present but only since the onset of the generalized itching dermatitis. Weight loss was absent. Typical pigmentation of the oral mucosa was present. The true significance of the widely distributed skin pigmentation was not at first appreciated, but was attributed to the long-standing dermatitis. Anorexia, nausea and vomiting were almost completely absent—the patient vomited only once after going into crisis. Until the onset of crisis he maintained a high blood pressure. This is not unusual in patients who have had a pre-existent hypertension,<sup>1-3, 18</sup> which this patient may well have had, on the basis of chronic glomerulonephritis.

Hypoglycemia was not present and the blood chloride was a low normal. The elevated blood urea nitrogen could be explained on the basis of chronic renal disease. A Kepler-Power water-diuresis test<sup>19</sup> would have been of no diagnostic value, since the presence of impaired concentrating power of the kidney would in itself cause a positive reaction. 17-ketosteroid excretion<sup>20</sup> could not be measured, since sufficient laboratory resources were not immediately available.

As the diagnosis of adrenal insufficiency was obscured by the presence of renal disease and a severe dermatitis, this combination presented definite therapeutic problems. The reason for the final hospitalization and the most pressing complaints was the severe dermatitis, and our first therapeutic efforts were directed against this problem. When full-blown Addisonian crisis did occur, the presence of renal disease probably contributed to the ineffectiveness of hormone therapy. Thorn, Dorrance and Day<sup>2</sup> imply that desoxycorticosterone acetate is contraindicated in cases of Addison's disease associated with hypertension. They found, in fact, resultant hypertension in some of the patients treated with desoxycorticosterone acetate, even in the absence of pre-existent hypertension. The action of adrenocortical hormones on the retention of sodium is dependent on an intact, functioning end-organ, the renal tubule. The presence of the tubular insufficiency as evidenced by a low urinary specific

FIGURE 2 Hematoxylin and Eosin Stain of Kidneys, Showing Chronic Glomerulonephritis (x350)

by 0.1 cm and weighed 1.3 gm. Grossly it was similar to the right, with the addition of small, pinhead-sized, nodular areas of yellow-tan cortex.

The kidneys together weighed 120 gm. They were equal in size, the right kidney was firm in consistence, and the capsule stripped with difficulty, tearing the gray tan granular cortex. The granules were irregular. On section the cortex measured 3 mm in diameter and was yellow gray, and the markings were indistinct. The medulla was purple gray, and the corticomedullary demarcation was indistinct. The mucosa of the renal pelvis was gray white and smooth. The left kidney was similar in appearance.

The remainder of the organs showed no gross lesions. The central nervous system was not examined.

On microscopical examination the important lesions were found in the suprarenal glands and the kidneys. The former showed the cortex to be present as nodular clusters of enlarged cells. Many of the cells contained a brown granular pigment in their cytoplasm. Cortical cells were seen, showing retrogressive changes as evidenced by remnants of cells and fragmented nuclei. Both cortex and medulla showed some fibrosis and lymphocytic infiltration (Fig 1).

The glomeruli of the kidneys were not uniformly affected. Many showed fibrosis of the glomerular tufts and fibrous adhesions between the lobules of the tufts and capsule. Rarely, glomeruli were converted into balls of fibrous tissue. Normal glomeruli were seen. The tubules in the region of the fibrosis showed atrophy. The interstitial and connective tissue was

\*Performed by Dr. Benjamin Newman, pathologist, Veterans Administration Hospital, Togus, Maine.

gravity may well have hastened the death of this patient.

It appears that even a small amount of adrenocortical tissue is adequate for body needs under ordinary circumstances.

The marked renal disease, by impairing over-all sodium chloride loss, may have modified to some extent the sodium chloride deficit that frequently precipitates Addisonian crisis.

In the presence of combined Addison's disease and kidney disease in which salt and water-hormone studies fail to distinguish between the two diseases, the levels of carbohydrate in the blood become very important as a diagnostic measure. In the case reported above the only recorded blood sugar determination was normal, which leads us to believe that even a small amount of adrenal cortex was adequate to maintain a normal fasting blood sugar.

Specific diffuse renal disease is no more common in Addison's disease due to idiopathic atrophy than one might expect on a basis of coincidence. When it is present, as in this patient, it poses problems regarding both early correct diagnosis and the effectiveness of specific therapy.

#### SUMMARY

A fatal case of idiopathic adrenal atrophy complicated by chronic glomerulonephritis is presented.

Specific diffuse renal disease is an unusual complication of Addison's disease. Its presence may make diagnosis and treatment more difficult.

## SPASM AND FIBROSIS OF THE SPHINCTER ANI DUE TO REFLEX ACTION\*

FRANCIS C. NEWTON, M.D.,† AND CHARLES A. MACGREGOR, M.D.‡

BOSTON

SPASM and fibrosis of the anal sphincter associated with a long history of marked constipation, tenesmus, mild intermittent abdominal cramps and an almost daily intake of cathartics is a rather frequently observed clinical entity about which little has been written, but which is important enough on occasions to suggest major but unnecessary surgery.<sup>1-3</sup>

Twenty-one cases are reviewed in the present study. These patients were first seen because of variable complaints. Some sought advice because of constipation alone. Others complained of tenesmus. The majority, however, complained of vague abdominal discomfort, intermittent mild abdominal cramps, a sense of pelvic fullness, anorexia, flatus and marked constipation. All the symptoms at first are of such mild character that the progress

of the disease is very insidious. And because it is so insidious and gradual, it is allowed to establish itself as a part of the patient's life before he is aware that it requires medical advice; it is considered a minor problem in hygiene, requiring only home remedies.

It is much more prevalent among women than men. Of the 21 patients, 19 were women. Possibly this is because women lead a less active and more sedentary life in general than men and thus are more prone to constipation. The average age was fifty-five years, the youngest patient being twenty-nine and the oldest eighty-seven. All but 2 gave a history of marked constipation needing almost daily cathartics for many years. All but 1 had some tenesmus. A few had had minimal or moderate rectal bleeding on occasions. Not one of the women had had any degree of prolapse, which is of interest in that constipation played a predominant part in the syndrome. Three patients stated that borborygmus was an annoying symp-

tom Eight stated that flatus was prominent Eight also complained of a sense of fullness in the pelvis Twelve had intermittent mild or moderately severe low abdominal cramps Six of the 21 patients also had anorexia or mild nausea, or both

The self-medication varied considerably but in general consisted of the taking of various forms

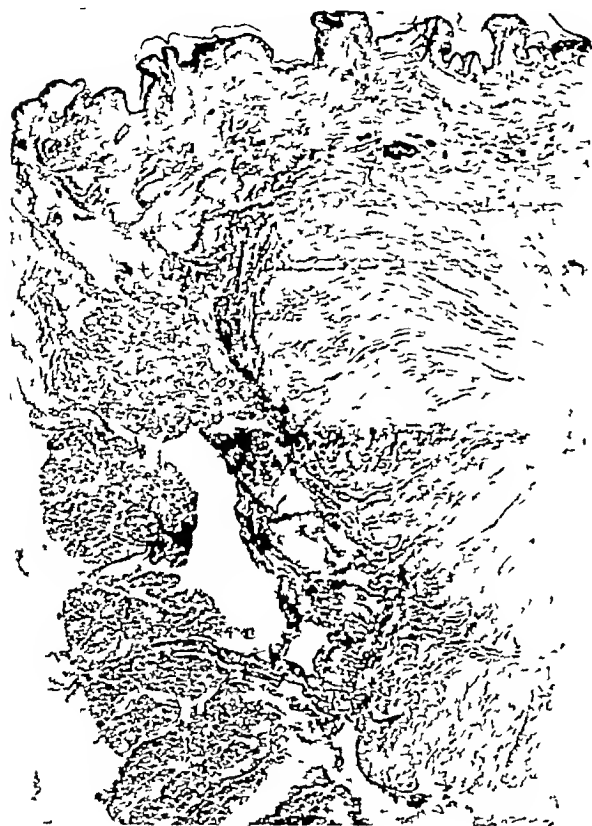

FIGURE 1 Longitudinal Section of a Normal Anal Canal at the Level of the Junction of the Internal and External Sphincters The internal sphincter consists of smooth muscle and is on the right A moderate amount of fatty subcutaneous tissue can be seen overlying the striated muscle of the external sphincter

of mild cathartics For example, 1 patient had taken approximately  $\frac{1}{2}$  pint of mineral oil daily for fourteen years She had started it fourteen years previously on her doctor's advice after a hemorrhoidectomy The vicious circle that was established is all too familiar to most proctologists<sup>1, 4, 5</sup> A second patient had moved her bowels only with the aid of enemas for seventeen years A third had been on a peptic-ulcer regimen for about five years with various constipating antacids and alkalis In all but 1 case there was a long history of frequent catharsis averaging ten to fifteen years

Physical examination always revealed a marked degree of spasm of the anal sphincter In many cases the examiner was unable to introduce even

the tip of his finger without causing considerable pain<sup>3</sup> Both the internal and external sphincters were found to be spastic, hypertrophied, hard and hyperirritable Moreover, in most cases, the internal sphincter was definitely smaller in diameter than the external

In 6 cases no other rectal or anal disease was found In 4, hypertrophied papillae or small anal polyps were present An additional 4 patients had very small external and internal hemorrhoids Five showed either a small established fissure in ano or areas of abrasion of the anal canal These associated pathologic conditions in no case seemed severe enough to have been the cause of the patient's symptoms Rather, they merely acted as an aggravating factor in the vicious circle of constipation, catharsis, spasm and fibrosis of the sphincter

A recent patient (P B B H L8421), with a history of excessive use of mineral oil daily for over twenty years, received dilatation and partial division of the external sphincter under general anesthesia Sigmoidoscopy was carried out at the same time, revealing two small polyps 12 and 18 cm from the anal canal These were excised and

FIGURE 2 Longitudinal Section of the Anal Canal in Case 5A327, Showing the Muscle Fibers of the External Sphincter Ten Days after Partial Division

on microscopical examination one proved to be malignant Accordingly, after suitable preparation, a combined abdominoperineal resection was carried out, thus giving an unusual opportunity for microscopical examination of the tissues in the region of the anus

Figure 1 demonstrates a longitudinal section of the anal canal at the junction of the external and internal sphincters The internal sphincter, which is smooth muscle (involuntary), is seen on the right, and the external sphincter, which is striated muscle

(voluntary), is on the left, separated by only a small amount of fibrous tissue. It is important to note the character of each muscle group and also of the small amount of fibrous and fatty tissue making up the subcutaneous layers.

Figure 2 presents a longitudinal section of the anal canal in the case mentioned above, demonstrating the effect of the partial division of the external sphincter. The striated muscle fibers show fatty degeneration and atrophy. There is only a moderate amount of fibrosis of the subcutaneous tissue, and this is most apparent overlying the internal sphincter.

One patient refused operation, but all others had a dilatation of the anal sphincters and partial division of the external sphincter.

In the following case, illustrating the need for accurate recognition of this diagnostic problem,

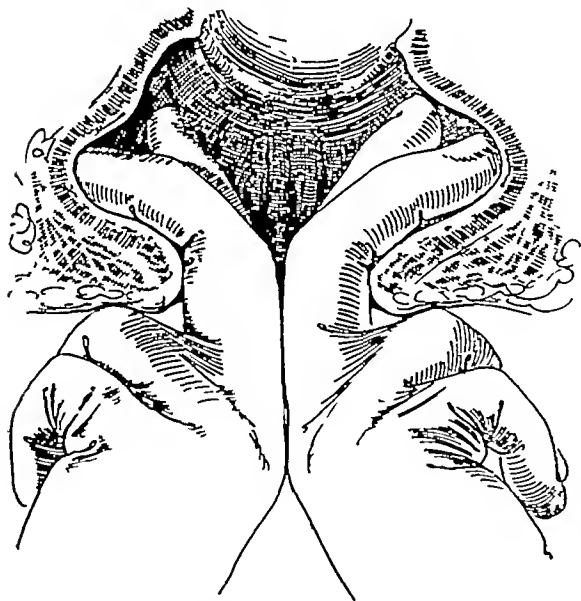

FIGURE 3 Procedure for Dilatation of the Anus

The gloved hands of the surgeon are covered with vaseline, and, with the dorsum of the hands approximated, the index fingers are inserted into the anus. The fingers are introduced full depth, moderately flexed, and then pulled outward as the hands are rotated slowly from side to side, increasing constantly a firm, persistent tension on the sphincter muscles. (Reproduced from Cutler and Zollinger<sup>8</sup> by permission of the publisher.)

the patient gave such a vague yet incapacitating history that abdominal exploration was carried out to rule out a chronic obstruction thought possibly due to adhesions or a slowly growing tumor.

L. M. (PBBH S45291), a 66-year-old single woman, was admitted to the hospital complaining of intermittent lower abdominal pain and occasional episodes of nausea. The pain was frequently relieved by the passage of flatus. She had also been troubled with severe persistent constipation requiring frequent catharsis and enemas. Mineral oil two or three times a day, followed by a cathartic in the evening had been her routine for many years. She stated

that her stools were usually partially fluid and that solid movements were very painful. There had been no bloody stools or protrusion of any rectal masses. No previous surgery had been carried out.

Physical examination of the abdomen was negative. Rectal examination revealed a firm stricture about 1.5 cm within the anal rim. This stricture appeared to be a contraction of the whole anal canal rather than a thin diaphragm.

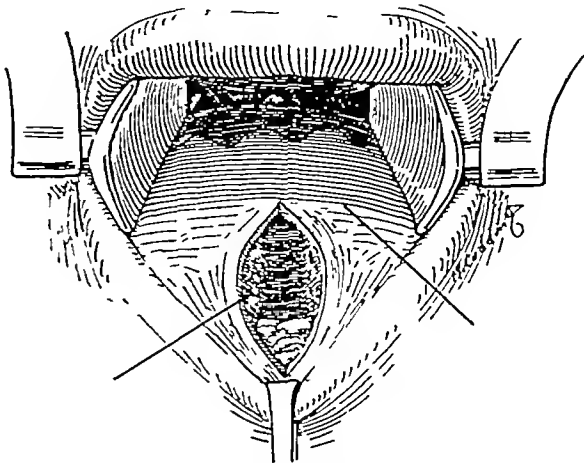

FIGURE 4 Incision of the Spastic External Sphincter

When necessary, the incision is made in the midline posteriorly and is carried only as deep as is necessary to obtain definite relaxation of the sphincter. Complete division is obviously to be avoided to avoid incontinence. Usually, however, the danger of this is minimal since the ridge of spastic tissue generally does not involve the entire sphincter.

The tip of the forefinger only could penetrate it, and attempts to dilate it were extremely painful. There was no blood on the examining finger.

Preoperatively, the diagnosis seemed obscure. It was difficult to see how the stricture of the anal canal could be the causative factor, because it was not tight enough to interfere at all with the passage of gas and the patient always had had loose stools.

Urinalysis and blood studies were negative.

A barium enema was normal. Exploratory laparotomy was carried out on the 4th hospital day under avertin and ether anesthesia, and very careful and thorough exploration revealed no disease. The appendix was removed as an incidental procedure and was later reported as normal by the pathologist. Immediately after the laparotomy, anal dilatation was performed, and an incidental small anal polyp noted. Two weeks later, excision of the small anal polyp was carried out. Further examination at that time revealed nothing additional. The polyp presumably played no part in the basic disease. The patient was discharged with bowel movements normal and free from tenesmus for the first time in 20 years.

Four years later the patient was seen and examined by the surgeon. She had been on a normal diet without laxatives or catharsis and had had normal bowel movements with only occasional tenesmus.

The treatment advocated consists of anal dilatation under a general anesthetic (Fig. 3). This should be carried out slowly (to avoid tearing of the muscle fibers, with resultant hematoma and fibrosis) over a period of ten minutes, until one is able to insert a total of four or five fingers to their full depth with ease. Frequently, one is forced partially to incise the external sphincter in the midline posteriorly because of a shelf-like hyperplasia

or even fibrosis of the tissue (Fig 4) This will be felt as a firm, unyielding ring just below (caudad to) the mucocutaneous junction Such incision is occasionally erroneously referred to as a pectinotomy It is well to carry out sigmoidoscopy or proctoscopy now if one has been unable because of the spasm to do so previously Also, hemorrhoidectomy, excision of polyp or curettage of a fissure, if indicated, should then be done

Local injections of an anesthetic to control points of discomfort are considered unnecessary since

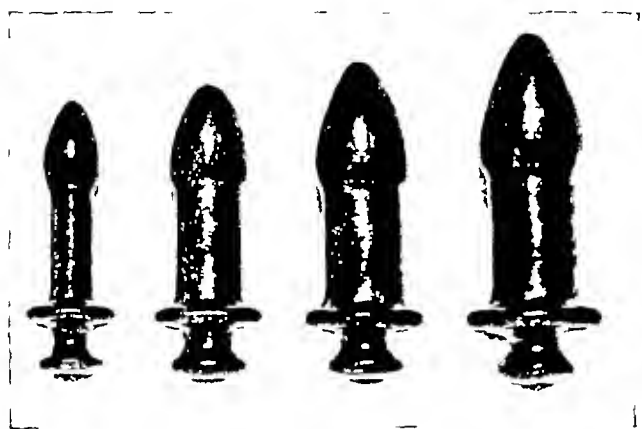

FIGURE 5 Young's Dilators

the dilatation itself prevents any painful spasm of the sphincter If the external sphincter requires partial division or other disease, such as hemorrhoids, polyps or fissures, has been present, the postoperative treatment should consist of clear fluids without milk for four days, followed by a gradual return to a normal high-residue diet without catharsis for the next two or three days If no abnormality other than spasm is found, a high-residue diet without catharsis may be resumed immediately Beginning on the fourth day in the uncomplicated case, rectal dilatation should be performed daily, either digitally or by the use of

Young's dilators (Fig 5) These consist of a series of graduated dilators, which may be passed by the patient with the aid of a small amount of lubricating jelly, beginning with the smallest and working up to the largest size each time The daily dilatation should be continued as long as is required to re-establish normal bowel habits Periodic rectal examinations should be made by the physician to detect any tendency to recurrence of the anal spasm

In the 21 cases in the present series, follow up reports varying from six months to five years give consistently good results Only 1 case required readmission for a second dilatation It is of interest that 2 cases showed extensive diverticulosis; quite possibly a result of the constipation and straining

### SUMMARY

A clinical entity of spasm and fibrosis of the sphincter ani, with marked constipation, chronic excessive use of cathartics and vague symptoms of abdominal discomfort, anorexia, cramps, tenesmus and flatus, is described and 21 cases reviewed

The incidence is far greater in women than in men

The average age when the disease is recognized is fifty-five years

The average duration of symptoms is ten to fifteen years

Treatment consists of anal dilatation with or without partial division of the external sphincter

Postoperative care should include a high-residue diet (unless diverticulosis is present) without catharsis and with anal dilatation by the patient and follow-up examinations by the physician

## SUCCINATE THERAPY IN ACUTE RHEUMATIC FEVER\*

RENÉ WÉGRIA, M D,<sup>†</sup> EDWARD E. FISCHEL, M D,<sup>‡</sup> AND PAUL E. WILSON, M D<sup>§</sup>

NEW YORK CITY

IN 1945, Gubner and Szucs<sup>1</sup> compared the efficacy of several drugs in the treatment of acute rheumatic fever. They reported that a group of patients treated with ascorbic acid and a succinate compound, subenon (calcium double salt of benzoic acid and succinic acid benzyl esters), introduced in 1936,<sup>2,3</sup> responded more favorably than a group of patients treated with ascorbic acid and salicylate. They stated that fever, leukocytosis and elevation of the erythrocyte sedimentation rate subsided more promptly, that carditis developed in fewer patients, that "relapses" of rheumatic activity were less frequent and that the average duration of the period of hospitalization was shorter in the patients treated with succinate. The purpose of this paper is to report the observations made on a small group of 10 patients treated with subenon.

## METHOD

Cases were selected in which a definite diagnosis of acute rheumatic fever could be established. To reach the diagnosis and to follow the course of the disease, the following clinical and laboratory data were used: history, physical examination, temperature, blood counts, erythrocyte sedimentation rate,<sup>4</sup> throat culture, antistreptolysin titer<sup>5</sup> and electrocardiogram. In most cases, therapy was instituted within forty-eight hours after admission, this time being used to establish the diagnosis and collect the necessary data. All the patients were given slightly larger doses of subenon (5.4 to 7.2 gm daily) than those in the studies of Gubner and Szucs<sup>1</sup> (4.0 to 5.3 gm daily), except 2 patients, five and nine years old, who received 3.6 gm every day. Two patients received some ascorbic acid. As Gubner and Szucs reported that the erythrocyte sedimentation rate returned to normal values within the first twenty-four days of subenon therapy in all their cases, we attempted to keep our patients on succinate therapy exclusively for at least three weeks. The results observed in a group of patients receiving either small or large doses of salicylate, reported in a previous study,<sup>6</sup> were used as a background to evaluate the course of the disease during subenon therapy.

## CASE REPORTS

**CASE 1** A 40-year-old Irish housewife, who had had a sore throat 4 weeks before admission, developed a temperature of 101°F and had pain in both hips and heels 4 days before admission. She was admitted to the hospital with the diagnosis of acute rheumatic fever. She was observed for 2½ days, during which the temperature ranged between 101 and 102°F, and the heart rate between 100 and 130. The sedimentation rate was 107 mm in 1 hour, and the white-cell count 13,000. Subenon (18 gm every 6 hours, day and night) was started on the 3rd day and continued for 12 days. Ascorbic acid 100 mg every day was also given from the beginning of the 2nd week. During the first 2 days of subenon administration, acute arthritis of both knees, elbows, wrists and all fingers, which required up to 500 mg of demerol a day, developed. Signs and symptoms of the rheumatic polyarthritis persisted until the administration of aspirin. On the fourth day of subenon administration, pericarditis developed, and a gallop rhythm was heard. The temperature ranged between 99 and 101°F, the heart rate remained unchanged. The white-cell count rose to 19,000, and the sedimentation rate to 119 mm in 1 hour, remaining above 110 until the 18th hospital day. On the 15th hospital day the sedimentation rate was still 113 mm in 1 hour. Signs and symptoms of the rheumatic polyarthritis had persisted. Subenon was stopped, and acetylsalicylic acid was given. The sedimentation rate began to fall steadily 4 days later, and the polyarthritis improved immediately.

During the administration of subenon, this patient with acute rheumatic polyarthritis showed no objective or subjective signs of improvement and developed myocarditis and pericarditis.

**CASE 2** A 5-year-old Negress who had had a sore throat 2 weeks before admission complained, 1 week before admission, of pain in both knee joints followed within 3 days by pain in the elbows and wrists. She was admitted to the hospital with a diagnosis of acute rheumatic polyarthritis. The temperature was normal. She had a sinus tachycardia (rate of about 120 per minute) and a normal PR interval. The sedimentation rate was 68 mm in 1 hour. Nose and throat culture revealed beta-hemolytic streptococci. The antistreptolysin titer was 832 units. Subenon (0.6 gm every 4 hours, day and night) was administered from the 2nd hospital day for 6½ weeks. Ascorbic acid (0.1 gm every day) was also given. The patient remained asymptomatic but kept having a marked sinus tachycardia (rate up to 160 per minute). At the end of the 4th week, she developed subcutaneous nodules. Her temperature remained normal except for an occasional day when it rose to 101.6°F. The sedimentation rate fell slowly from 68 to 46 mm in 1 hour at the beginning of the 3rd week, rose within 1 week to 83 mm and fell slowly to 53 mm by the middle of the 7th week. At that time a gallop rhythm developed, and subenon was discontinued.

During six weeks of subenon therapy, this patient developed subcutaneous nodules and gallop rhythm and kept having febrile episodes. The sedimentation rate after an initial slight decrease, rose to higher levels than on admission and was still markedly elevated at the end of the period of subenon administration.

**CASE 3** A 9-year-old girl had had a sore throat, acute catarrhal otitis media and migratory polyarthritis 2 weeks

\*From the departments of Medicine and Pediatrics, Presbyterian Hospital and Columbia University College of Physicians and Surgeons. This study was aided by a grant from the Life Insurance Medical Research Fund.

<sup>†</sup>Associate in medicine, Columbia University College of Physicians and Surgeons, assistant physician, Presbyterian Hospital.

<sup>‡</sup>Fellow in medicine, Columbia University College of Physicians and Surgeons, assistant physician, Presbyterian Hospital.

<sup>§</sup>Assistant in pediatrics, Columbia University College of Physicians and Surgeons, assistant pediatrician, Presbyterian Hospital.

before admission. One week before admission, she was given sulfadiazine and aspirin. She was admitted to the hospital with a diagnosis of acute rheumatic polyarthritis. During 2 days of observation, her temperature ranged between 101 and 104°F, and her heart rate between 100 and 120. The sedimentation rate was 110 mm in 1 hour. Rough systolic and diastolic murmurs heard at the apex were thought to be due to a previous subclinical attack of rheumatic valvulitis. On her 2nd hospital day the administration of subenon (0.9 gm every 6 hours) was begun. Her temperature remained between 101 and 104°F. There was an increase in symptoms and signs of the polyarthritis, and several additional joints became involved. The sedimentation rate rose from 110 to 132 mm in 1 hour on the 6th day of subenon therapy and varied between 100 and 110 mm for the next 2 weeks. An electrocardiogram taken on the 14th day of subenon therapy revealed that, with the same heart rate as before, the PR interval had risen from 0.14 to 0.24 second. Because 18 days of subenon therapy had not brought about any improvement in symptoms or signs, it was discontinued. The institution of salicylate therapy was followed by a rapid drop of the temperature and a return of the PR interval to normal (0.16 second) within 4 days.

In this case of acute rheumatic polyarthritis subenon did not produce any subjective or objective improvement and did not prevent the involvement of other joints and the appearance of a marked prolongation of the PR interval.

**CASE 4** A 49-year-old Negro with hypertensive and arteriosclerotic heart disease had had acute rheumatic polyarthritis 7 years before admission. Three weeks before admission, the patient had an upper respiratory infection followed 1 week later by acute migratory polyarthritis. He was admitted to the hospital with a diagnosis of acute rheumatic polyarthritis. On the 2nd hospital day, the administration of subenon (12 gm every 4 hours) was begun and continued for 36 days. The temperature ranged between 100 and 102°F and became normal after 1 week. The sedimentation rate, which was 70 mm in 1 hour on admission, rose to 100 mm within 10 days and remained between 100 and 110 mm for another 3 weeks. After 37 days of hospitalization (36 days of subenon therapy), it was still 90 mm. Demerol and codeine were used to control the joint pain, which persisted throughout the 5 weeks of subenon therapy. Additional joints became involved during the same period. Digoxin and mercurial diuretics, which the patient had been receiving for 2 years because of cardiac failure due to arteriosclerotic heart disease, were continued. On admission, a throat culture yielded a hemolytic streptococcus. Penicillin (10,000 units by intramuscular injection every 4 hours) was also given from the 3rd to the 22nd hospital day. Subenon was discontinued after 36 days of administration. The patient then received acetyl salicylic acid, which was promptly followed by the usual subjective and objective signs of improvement of the arthritis. The sedimentation rate fell to 22 mm in 1 hour after 25 days of salicylate therapy.

In this case of acute rheumatic polyarthritis the temperature became normal after twelve days of subenon administration. The patient, however, kept having signs and symptoms of acute polyarthritis and developed arthritis in joints previously not involved. The sedimentation rate rose markedly during subenon administration, remained elevated and was still 90 mm in 1 hour—that is, higher than on admission—after five weeks of subenon therapy.

**CASE 5** A 16-year-old boy, who had had chills and fever 3 weeks before admission and a sore throat 2 weeks before admission, developed acute migratory polyarthritis of the knees, ankles and toes 1 week before admission. He was admitted to the hospital with a diagnosis of acute rheumatic polyarthritis. From the 2nd hospital day, he received 12 gm of subenon every 4 hours, day and night, for 32 days.

His temperature, which ranged between 102 and 103°F for 6 days, returned to normal within 10 days and remained normal thereafter. The signs and symptoms of arthritis persisted for 9 days, and during that period, additional joints became involved. Large amounts of demerol and codeine had to be used to control the pain. The sedimentation rate, which was 108 mm in 1 hour on admission, was 118 and 103 mm respectively on the 7th and the 12th hospital day. By the 16th hospital day it was 57 mm, and it then came down progressively to normal (20 mm or less) by the end of the 4th hospital week. The PR interval, which was 0.18 second on admission, with a heart rate of 87 per minute, was 0.20 second on the 6th hospital day, with a heart rate of 80, on the 25th hospital day, it was 0.16 second, with a heart rate of 70. Subenon therapy was discontinued after 32 days. The patient was discharged home well after a period of 49 days in the hospital.

In this case of acute rheumatic polyarthritis, probably with mild rheumatic myocarditis, there was clinical improvement with subenon, and the sedimentation rate came down to normal on the twenty-sixth day of subenon administration.

**CASE 6** A 42-year-old Negress who had had a sore throat 4 weeks before admission developed acute arthritis of the left knee 1 week before admission and 2 days later had pain in the right hip. She was admitted to the hospital with a diagnosis of acute rheumatic polyarthritis. Her temperature was 102°F, the sedimentation rate 88 mm in 1 hour, and the antistreptolysin titer 712 units. The administration of subenon (12 gm every 4 hours) was begun on her 3rd hospital day and continued for 18 days. Until the end of this period, heavy doses of demerol and codeine had to be used for the arthralgia, and the patient developed arthritis of the elbows, shoulders and wrists. Her temperature ranged between 100 and 104°F throughout the period of subenon administration. The sedimentation rate, which rose to 130 mm in 1 hour on the 4th day, was 127 mm on the 14th day and 110 mm on the 18th and last day of subenon administration. The PR interval, which was 0.18 second on admission, rose to 0.24 second with a slightly higher heart rate on the last day of subenon therapy. The administration of subenon was stopped after 18 days. The patient was then given sodium salicylate and improved.

Although treated with subenon, this patient continued to have fever and migratory polyarthritis, the sedimentation rate rose, remaining markedly elevated. The PR interval became prolonged after eighteen days of subenon therapy.

**CASE 7** A 7-year-old girl who had had a severe sore throat 3½ weeks before admission had fever and a mild knee ache 3 days before admission. She was admitted to the hospital with a diagnosis of acute rheumatic arthritis and rheumatic myocarditis. Her temperature was 103°F, the sedimentation rate 106 mm in 1 hour, and the PR interval 0.20 second, with a heart rate of 130 per minute. The administration of subenon (0.9 gm every 4 hours) was begun on the 3rd hospital day and continued for 21 days. The symptoms of arthritis were very mild and transient before any therapy and could not be used to evaluate the course of the disease. The patient's temperature, ranging between 100 and 103°F during the control period, fell gradually to normal within 1 week of hospitalization. The sedimentation rate, which was 106 mm in 1 hour on admission, was 102, 67 and 62 mm after 4, 10 and 17 days of subenon administration, respectively. The heart rate and the PR interval decreased progressively. The PR interval, which was 0.20 second with a heart rate of 130 on admission, was 0.20, 0.17 and 0.16 second with a heart rate of 90 per minute after 4, 10 and 17 days of subenon therapy, respectively. The patient was discharged home on the same regimen after 21 days of subenon therapy. Fourteen days later, when seen in the clinic, she was well, but her sedimentation rate was still 55 mm in 1 hour.

In this case of acute rheumatic fever with mild monoarthritis and myocarditis, the patient improved clinically, but the sedimentation rate was still markedly elevated after twenty-one days of subenon therapy. After another fourteen days of subenon therapy at home, the sedimentation rate was still 55 mm in 1 hour.

**CASE 8** A 14-year-old girl, who had had chorea at the age of 10, had a sore throat 1 month before admission and intermittent fever with a mild ache in the left foot for the 10 days preceding admission. She was admitted to the hospital with a diagnosis of acute mild rheumatic polyarthritis and myocarditis. On admission she had a mild ache in the left knee and both hips. Her temperature was 100.4°F and never rose above 101°F. The sedimentation rate was 55 mm in 1 hour. The administration of subenon (12 gm every 4 hours) was begun on the 3rd hospital day and continued for 32 days. The joint pains, which were mild even during the control period, subsided gradually although she kept having an occasional pain in other joints than those involved on admission. The sedimentation rate rose from 55 to 86 mm in 1 hour by the sixth day of subenon therapy and was 70, 50, 55 and 50 mm after 13, 20, 22 and 29 days of subenon administration respectively. The electrocardiogram taken on admission showed nodal tachycardia, when the next electrocardiogram was taken 2 weeks later, the patient had converted to regular sinus rhythm with a heart rate of 80 and a PR interval of 0.20 second. The PR interval was still 0.20 second after 25 days of subenon therapy. After a 32-day period of subenon administration the sedimentation rate was still 50 mm, and sodium salicylate therapy was begun. After 21 days of salicylate administration, the sedimentation rate became normal, and the PR interval was 0.18 second with a heart rate of 65.

In this case of mild acute rheumatic fever no obvious effect of subenon was noted on the sedimentation rate or the electrocardiogram, the only criteria available in the study of this case.

**CASE 9** A 17-year-old boy, who had had acute rheumatic polyarthritis at the age of 8, had a pharyngitis 1 month before admission, and joint pains during the week preceding admission. He was admitted to the hospital with a diagnosis of acute rheumatic polyarthritis, involving both knees and ankles, with acute myocarditis. On the first hospital day, his temperature ranged between 101 and 102°F, and his heart rate between 100 and 130. The sedimentation rate was 55 mm in 1 hour. An electrocardiogram showed a PR interval of 0.26 second, with a ventricular rate of 100. On the 2nd hospital day the administration of subenon (12 gm every 4 hours day and night) was started, and it was continued for 34 days. Large amounts of demerol were required for analgesia. The patient's temperature remained above 101°F for the first 6 days of subenon administration, and dropped to between 100 and 101°F during the following week, after which it became and remained normal until the end of the 6th week of hospitalization. On the 2nd hospital day the patient developed acute pericarditis. The sedimentation rate rose to 118 mm in 1 hour on the 5th day of subenon administration, decreasing gradually to 45 mm by the end of the 5th week. At that time, the joint pains had progressively subsided, the PR interval had gradually decreased to 0.20 second with a ventricular rate of 84, and subenon was discontinued. One week later, the patient's temperature rose to 101°F, and the sedimentation rate to 61 mm in 1 hour. The joint pains reappeared, and the PR interval increased to 0.24 second. The administration of subenon was resumed for another 29 days. At the end of that period, the symptoms had gradually subsided, the sedimentation rate kept varying between 20 and 35 mm in 1 hour, and the PR interval was still 0.22 second, with a ventricular rate of 75. The patient was then given sodium salicylate and continued to improve.

In this case of acute rheumatic fever (polyarthritis, myocarditis and pericarditis) the sedimentation

rate was still elevated after thirty-four days of subenon therapy. It is impossible to establish the nature of the episode that occurred after the administration of subenon had been discontinued, but it was very similar to what is observed in cases of acute rheumatic fever in which aspirin therapy is discontinued prematurely although in such cases, recrudescence of rheumatic activity becomes obvious within a shorter time.<sup>7</sup>

**CASE 10** A 14-year-old girl, who had had a sore throat 1 month before admission, developed migratory polyarthritis 11 days before admission. She was admitted to the hospital with a diagnosis of acute rheumatic polyarthritis. During the first 3 days of her stay in the hospital, her temperature ranged between 100 and 103°F, and on the 4th day it was about 100°F. The administration of subenon (0.6 gm every 6 hours for 2 days and then 1.5 gm every 6 hours for 20 days) was begun on the 5th hospital day. No analgesics were required either before or during the administration of subenon. The temperature, which fell steadily during the period of observation, became normal and remained normal from the 6th hospital day. The sedimentation rate was 43 mm in 1 hour on admission, rising to 60 mm on the 3rd hospital day, it was 52, 45, 22 and 22 mm respectively, on the 2nd, 5th, 9th and 12th days of subenon administration. The rate then rose progressively, being 26, 36 and 41 mm, respectively, on the 14th, 19th and 22nd days of subenon therapy. It was then decided to place the patient on salicylate therapy. The sedimentation rate became normal after 3 weeks of salicylate therapy.

In this case of mild acute rheumatic polyarthritis the sedimentation rate, the only constant sign of rheumatic activity, fell to almost normal after ten days of subenon therapy but rose again while the patient was receiving subenon.

## DISCUSSION

Ten patients with acute rheumatic fever were given subenon (a succinic acid derivative) in doses reported to be adequate for fifteen to forty-six days and were followed carefully. Comparing this series of patients receiving succinic acid therapy with another series of patients receiving small or large doses of salicylates,<sup>8</sup> we can see no reason to believe that the succinic acid derivative is beneficial in acute rheumatic fever. It does not have any of the marked analgesic and antipyretic properties of salicylate. It does not prevent, as salicylate usually does, the involvement of additional joints by the rheumatic process. It does not prevent the appearance of signs of myocarditis any more than salicylate does. After the administration of succinic acid had been discontinued, several patients were given aspirin or salicylate and proved not to be cases refractory to treatment such as are occasionally seen.<sup>6</sup> In view of the comparatively poor results obtained with subenon, more cases were not studied.

## SUMMARY

Ten cases of acute rheumatic fever treated with subenon are reported. Neither the natural course of the disease nor its signs or symptoms were modified by the treatment.

## MEDICAL PROGRESS

## PHYSIOLOGY (Continued)\*

HEBBEL E. HOFF, M.D.,† AND H. J. SCOTT, M.D.‡

MONTREAL, CANADA

An idea of the discreteness of the efferent control via the cortex is given by the evidence reported by Chang, Ruch and Ward, who with fixed routine of stimulation were able to delimit cortical areas controlling separately a single muscle operating at the ankle of the monkey, or even single parts of a muscle. Although it is clear from the work of Sherrington himself on the instability of motor points on the cortex that no entirely rigid anatomic pathway is responsible for these results, it is equally clear that out of a combination of anatomic pathway and stimulation characteristics a physiologic connection between cortex and spinal cord is open by which individual muscles or their parts can be reached.

If, then, the pyramidal system and for that matter the extrapyramidal also are to be regarded more in the nature of final common pathways or internuncial relay systems it becomes necessary to look elsewhere for centers of control or regions of decision, not necessarily in the sense of cortical areas but also in the sense of neuronal pattern. Here three general phenomena must be considered.

**Reverberating circuit.** Soon after it was found that area 4 S acts to diminish cord reflexes, presumably by extrapyramidal projections that eventually reach the spinal segments, it was observed that the same area suppresses electrical activity in the precentral cortex operating by a separate circuit through the thalamus.<sup>41</sup> Area 8 is presumably also a suppressor area operating in the same manner, and Penfield and Rasmussen<sup>42</sup> have recently shown that Broca's area can probably be considered to be part of the area 8 suppressor system, because stimulation of this area in man sometimes produced arrest of speech without associated movement or sensation.

To such corticocortical circuits through basal ganglia and thalamus can be added circuits that pass through the cerebellum, and in fact the whole of the neocortex of the cerebellum can be considered to be occupied with a long circuit from cortex to the pons, through to the cerebellum and back to the cortex via the thalamus. Basically the paleocerebellum represents a circuit from somatic and vestibular afferents back to the motor system. All represent in various degrees systems whereby activity sets up a chain of reaction by which in turn activity is regulated. To these long-chain reverberating circuits must also be added short chain-circuits within the cortex itself changing the whole relation of afferent and efferent systems from a simple stimulus-response reaction with a short time course to a continuous self-regulation with a long time scale.

**Self-generated rhythm.** Continued neuronal activity for long periods after cessation of input can and undoubtedly does occur by virtue of the long delay paths that the neuronal organization of the central nervous system affords. But there is also evidence that many cells are in themselves spontaneously rhythmic, or are capable of being stimulated to rhythmic activity in the proper circumstances, just as a quiescent frog heart is often brought back to regular spontaneous beating by a few adequate stimuli.

Larrabee and Bronk<sup>43</sup> have noted prolonged afterdischarge, after strong presynaptic stimulation in the sympathetic ganglion where the question of delay paths cannot arise, and Adrian<sup>18</sup> has recorded prolonged afterdischarge from thalamic nuclei after afferent stimulation. Too little is known of the rhythms within the central nervous system, however, for one to be entirely certain what part rhythmic discharge of a single unit and what part rhythmic activity based on interneuronal circuits, respectively, play in the final picture as recorded.

**Field effects.** Thus far the concept has developed of an orderly though complicated interrelation of

cells via synaptic junctions. But it is well to remember that the interrelations of neurones may transcend this orderly pattern. The electrical fields surrounding an active tissue may alter the state of surrounding cells without reference to synaptic junction in a variety of ways. In the proper circumstances adjacent cells may be directly excited, this is the basis for the well known phenomenon of the rheoscopic frog first described by Matteucci, who noted the contraction of a frog muscle whose isolated nerve was looped over the belly of a first-nerve-muscle preparation when this was stimulated. Such field effects are responsible for the reflex volleys seen to emerge from dorsal roots after a single afferent volley as observed by Toennies<sup>44</sup> and for transmission at the artificial synapse as described by Granit<sup>45</sup> in which an impulse descending via a motor fiber becomes able to set up impulses in adjacent dorsal-root fibers at a region of injury or transection. Whether this type of extrasynaptic transmission ever has any real biologic value is problematical, but the suggestion that the poorly adapting pain fibers involved in a region of nerve injury are stimulated by impulses descending via sympathetic fibers constitutes one of the most attractive theories of the genesis of causalgia<sup>45, 46</sup>. Even when by virtue of threshold, geometry or distance the active fiber does not directly evoke an impulse in surrounding tissue, it may condition its activity by inhibiting or facilitating excitation in it. Thus, Segers et al.<sup>47, 48</sup> have shown that excised sections of frog's ventricle beating independently come into synchronization when placed close enough together, and Fessard<sup>49</sup> has demonstrated the same phenomenon in isolated segments of electrical organs. Much of this work dates from Arvanitaki's<sup>50, 51</sup> earlier studies. Bremer<sup>52, 53</sup> induced rhythmic potentials in the frog's spinal cord by strychnine poisoning and found that even after section of the cord the rhythms in the two isolated segments were synchronous, presumably by reason of interaction of the electrical fields of the two segments. Gerard<sup>54, 55</sup> has elaborated this hypothesis most actively in regard to the central nervous system and has listed the following aspects of central-nervous-system function as being more readily explainable on the basis of these field effects than in terms of transmission through established neuronal patterns<sup>56</sup>: the synchronization of spontaneous neurone firing, the establishment of new neuronal connections between brain centers in conditioning, central-nervous-system inhibition, functioning of the cortex in learning, summation of excitatory and inhibitory impulses reaching separate neurone processes, total behavior patterns and the phenomena of sensory equivalent.

But although Bremer considered the persistence of synchronization between anatomically separated segments of the spinal cord as evidence of the action of field effects, Sperry<sup>56</sup> interprets failure of subdivision of the sensorimotor cortex by gridiron incision

to affect the co-ordination of movements of shoulder, elbow, wrists and digits or to produce deficiency in capacity for motor learning as having quite the opposite significance, believing that the self-propagating intracortical potentials cannot spread their excitatory effect across a fresh cut in the mammalian cortex. If the evidence Sperry adduces does have this significance it means that superficial horizontal association is much less important than the deeper and more vertical intercortical communications. Whatever functional importance spontaneous rhythms and field effects may in the future prove to have, they serve at present as a valuable corrective to thinking of the nervous system as a telephone switchboard for the connection of ingoing and outgoing calls, however complicated it may be.

*Contact utile between physical and psychic*. This is the final problem with which the physiologist is confronted, and indeed it is the greatest of his responsibilities to elucidate psychologic events in terms of neurophysiology. Sherrington<sup>5</sup> recognized this when he wrote in the foreword of the 1947 edition of *The Integrative Action of the Nervous System*.

There remains yet another type of integration which claims consideration, although to saddle it upon nerve may perhaps encounter protest. Integration has been traced at work in two great, and in some respects counterpart, systems of the organism. The physico-chemical (or for short physical) produced a unified machine from what without it would be merely a collocation of commensal organs. The psychical, creates from psychical data a perceptive, thinking and endeavouring mental individual. Though our exposition kept these two systems and their integrations apart, they are largely complementary and life brings them co-operatively together at innumerable points. Not that the physical is ever anything but physical, or the psychical anything but psychical. The formal dichotomy of the individual, however, which our description practised for the sake of analysis, results in artefacts such as are not in Nature. Each such is a quasi-organism which does not resemble ourselves, nor does it, *pace* Descartes, resemble dog or cat. For our purpose the two schematic members of the puppet pair which our method segregated require to be integrated together. Not until that is done can we have before us an approximately complete creature of the type we are considering. This integration can be thought of as the last and final integration.

But theoretically it has to overcome a difficulty of no ordinary kind.

To this problem Sherrington was forced to conclude that the time has not yet arrived when one can insist, on the basis of precise knowledge, on the identity of the two.

In all those types of organism in which the physical and the psychical coexist each of the two achieves its aim only by reason of a contact utile between them. And this liaison can rank as the final and supreme integration completing its individual. But the problem of how that liaison is affected remains unsolved, it remains where Aristotle left it more than 2000 years ago. There is, however, one peculiar inconsistency which we may note as marking this and many other psychological theories. They place the soul in the body and attach it to the body without trying in addition to determine the reason why, or the condition of the body under which such attachment is produced. This, however, would seem to be a real question. Instead of, as is usual in physiology, leaving that impasse unmentioned, it seemed better to draw attention to it by the experimental observations in this book's final chapter.

Ritchie,<sup>3</sup> summarizing Sherrington as a philosopher, put the problem and its lack of solution in equally well turned phrases

In the purely material realm things and processes, though in some respects continuous, are in other respects "granular," wrapped in bundles all separate and all similar—the quantum of action, the electron, the atom, the molecule. In the organic realm there are also "granular" entities on a larger scale that are fundamental—the gene, the nervous impulse, the cell. There is in addition a process of co-ordination or integration at work, operating through purely physical and chemical means, yet exemplifying an order over and beyond the physical order. In spite of this integration, the most elaborately integrated of all organisms, the human, though possessing a master organ, the brain, possesses no master cell. Instead, the highest centres of the brain appear to be a kind of republic of millions of cells. Where does the mind come in? Mind is certainly not granular in the way that atoms and nervous impulses are. It is not a special kind of matter or of energy, as earlier speculators often suggested.

The bodily organism which contains millions of cells can do a number of things simultaneously by means of reflexes and acquired habits, but the mind attends to one thing at a time. It goes so far as to see one visual field through the medium of two distinct organs. Moreover, for a great deal of psychology knowledge of brain function is irrelevant. This is seen equally in the modern work of the psychoanalytic school and the many excellent psychological observations of Aristotle, who associated the heart, not the brain with conscious life.

Gerard<sup>54</sup> recognized the problem equally well but expressed it more forcefully

It remains sadly true that most of our present understanding of mind would remain as valid and useful if, for all we knew, the cranium were stuffed with cotton wadding. In time the detailed correlation of psychic phenomena and neural processes will surely come, but today we are hardly beyond the stage of unequivocal evidence that the correlation does exist.

Here Gerard has shown more courage than Sherrington, and it is perhaps significant to recall that when Bernard Sachs first met Freud in Meynert's Clinic, Freud "devoted himself to anatomy like the rest of us."<sup>55</sup>

### CATHETERIZATION OF THE HEART

The value of a new technic is measured not only by the success with which it meets the criteria for which it was introduced but also by the manner in which it opens new and hitherto unrealized approaches to research. One of the most striking illustrations of this is afforded by the method of intravenous catheterization whose application to human physiology must be credited almost entirely to Cournand and his collaborators<sup>58, 59</sup>. Naturally enough, the method has a fairly long background in physiology, although perhaps Chauveau and Marey<sup>60</sup> gave the greatest initial impetus by devising the catheters and transmission systems whereby right and left ventricular curves could be recorded from the intact unanesthetized horse. Sir Charles Sherrington often related to his classes the experience of visiting Chauveau's laboratory at Lyon, where ventricular pressure curves were demonstrated from a horse tranquilly eating hay outside the opened classroom window. In 1929

Forssmann<sup>61, 62</sup> demonstrated that the technic could be applied to man, by introducing a catheter into his own right auricle from a vein at the left elbow. Forssmann had intended the technic to provide a safe direct route for intracardiac injection of drugs, and reported its use in a patient with peritonitis following rupture of an inflamed appendix. The catheter remained in place six and a half hours before the patient died, but at autopsy no signs of damage to the intima or valves of the vessels in which it lay were noticed. The tip of the catheter had passed into the inferior vena cava. In the early years that followed Forssmann's report, the method was employed mainly as a means for introducing substances directly into the heart (not drugs, as Forssmann had intended, but radio-opaque materials for roentgenographic study of the heart and great veins), and this still remains one of its most important usages, despite the difficulty of injecting the material rapidly enough through the catheters usually employed, with a larger catheter (size No 12 to 14) introduced via the jugular vein more adequate rates seem to have been achieved.<sup>63</sup>

It was, however, its value in permitting determination of cardiac output according to the so-called Fick principle that gave the method the importance in human physiology that it holds today. In 1870 Fick<sup>64</sup> called attention to the possibility of calculating cardiac output from the quantity of oxygen or carbon dioxide in arterial and venous blood and the uptake of oxygen or output of carbon dioxide in a given time. This report, only two paragraphs in length, deserves translation and quotation in full.

Herr Fick gave a lecture on the measurement of the quantity of blood ejected by the ventricle of the heart in each systole, a figure the determination of which is without doubt of the greatest importance. Nevertheless the most different opinions thereof have been given. While Th. Young placed the value in question at 45 cc., the newer textbooks of Physiology give much higher values, which, based on the estimations of Volkmann and Vierordt run as high as 180 cc. In such circumstances it is unusual that no one has yet hit upon the following obvious method by which this important value may be determined directly, at least in animals. One determines how much oxygen an animal takes out of the air in a given time and how much carbon dioxide it gives off. During the experiment one obtains a sample of arterial and a sample of venous blood. In both the content of oxygen and the content of carbon dioxide are to be determined. The difference in oxygen contents tells how much oxygen each cubic centimeter of blood takes up in its course through the lungs, and since one knows the total quantity of oxygen absorbed in a given time, one can calculate how many cubic centimeters of blood passed through the lungs in this time, or, if one divides by the number of heartbeats in this time, how many cubic centimeters of blood are ejected with each beat of the heart. The corresponding calculation with the quantities of carbon dioxide gives a determination of the same value, which controls the first.

Since two gas pumps are required to carry out this method, the lecturer is unfortunately not able to report experimental findings. He will therefore give only a calculation of the extent of the circulation in man according to the schema of the method here described, based on more or less arbitrary data. According to experiments carried out by Scheffer in Ludwig's laboratory one cc. of arterial

blood of the dog contains 0.146 cc of oxygen (measured at 0° temperature and 1 meter Hg pressure), 1 cc. venous dog's blood contains 0.0905 cc of oxygen. Each cubic centimeter of blood takes up in its passage through the lungs 0.0555 cc. Assume that this were also true in man. Assume further that a man absorbs 833 g of oxygen out of the air in 24 hours. At 0° and 1 m. pressure this would occupy a space of 433,200 cc. Accordingly 5 cc's of oxygen would be absorbed by the lungs every second. In order to make possible this absorption there must, however, according to the above assumption,  $\frac{5}{0.0555}$  cc of blood flow through the lungs, or 90 cc. Assuming finally 7 systoles take place in 6 seconds, 77 cc of blood would be ejected with each systole of the ventricle.

Fick apparently never achieved, and perhaps never attempted, the actual experimental determination, and it remained for Gréhan and Quinquaud<sup>65</sup> and soon thereafter, Zuntz, to make the first experimental trials in animals. Technical difficulties must have been responsible for the virtual lapse of the method, even in animals, and until its recent revival by Cournand and his associates, few reports of its employment appeared, although an outstanding contribution by Marshall<sup>66</sup> (employing direct cardiac puncture) demonstrated that consistent and repeatable results could be obtained for extended periods.

So far as man is concerned the attempt was made from the first to devise an indirect method to avoid direct sampling of arterial and mixed venous blood, and the most successful of these at first rotated around the analysis of the carbon dioxide content of alveolar air. Normally, the alveolar air is in equilibrium with arterial blood, and from its concentration and a knowledge of the carbon dioxide dissociation curve of a given sample of blood, the arterial content of carbon dioxide could be calculated. The carbon dioxide of mixed venous blood was estimated by a variety of ingenious methods involving rebreathing from one or a series of bags containing carbon dioxide at concentrations up to 10 per cent or occlusion by intubation of part of the bronchial tree<sup>67, 68</sup>. All these methods required co-operation and even training for successful accomplishment, but still retain actual and theoretical usefulness in that they involve a determination of the actual composition of pulmonary capillary blood, and become important, as shall be seen later, in cases in which collateral vessels supply blood to the pulmonary capillaries beyond the larger ramifications of the pulmonary artery.

The methods employing foreign gases came ultimately, in the acetylene methods as developed by Grollman,<sup>69</sup> to be a procedure of arriving indirectly at the Fick calculation, for in it the rebreathing technic furnished basically the relative rates of absorption of oxygen and acetylene from the rebreathing system and the data of partial pressures of acetylene by which the quantity of acetylene absorbed by a given volume of blood could be calculated. From this figure, as well as from the ratio of oxygen to acetylene absorption, the amount of oxygen ab-

sorbed by a quantity of blood in the lungs could be computed—in other words the arteriovenous oxygen difference essential to the Fick calculation. Theoretically faultless, the whole determination must be made while the blood circulating through the lungs contains no recirculating acetylene, otherwise, actual absorption of acetylene will be less than calculated, and in consequence the calculated oxygen absorption will be too high, and the cardiac output proportionally too low.

The appearance of the first reports by Cournand and his associates thus placed the cardiac output of man on a sound experimental basis and gave a reference point by which other methods of great potential value such as the ballistocardiograph<sup>70</sup> could be calibrated. Moreover, it forced the reinvestigation, in terms of a direct experimental approach on man, of many concepts gained from animal experiments and has, paradoxically, renewed interest in animal experimentation, focusing attention upon the cardiovascular system in circumstances as normal as possible and not as isolated components in a heart-lung preparation.

One of the most important of the concepts that comes up for revaluation is the question of regulation of cardiac output. Here the clear-cut experiments of Patterson and Starling<sup>71, 72</sup> on the heart-lung preparation, demonstrating a direct proportionality between cardiac output and venous pressure and raised to the status of a "law of the heart," have long dominated thinking. Nor does the newer approach lead everyone to abandonment of it as a guiding principle. McMichael and Sharpey-Schafer<sup>73</sup> considered that cardiac output was regulated by at least three factors: venous pressure according to Starling's law, the heart rate and epinephrine. Sharpey-Schafer<sup>74</sup> found that anemic patients had a higher than normal cardiac output despite a diminished blood volume, which he related to the increased right auricular pressures observed. Normal persons responded to increased auricular pressure induced by rapid transfusion by marked augmentation of cardiac output. Right auricular pressures in normal persons were closely grouped around -4 cm of saline solution above the sternal angle, and cardiac outputs ranged from 4 to 7 liters. During transfusion pressures rose by 5 to 12 cm of saline solution, and outputs rose as high as 11 liters per minute. On the other hand auricular pressures in anemic patients ranged from slightly below 0 cm of saline solution to +12 cm, and in only 1 of the 7 cases (and that one with a relatively low venous pressure) did transfusion increase output. In all the rest output fell. Sharpey-Schafer concluded that anemic patients have already exploited to the full the benefits of Starling's law, and are at the part of curve where increasing diastolic stretch hampers ventricular contraction. In keeping with this concept is the report by Howarth, McMichael and Sharpey-Schafer<sup>75</sup> that venesection improves car-

## MASSACHUSETTS MEDICAL SOCIETY

## PROCEEDINGS OF THE COUNCIL

Annual Meeting, May 24, 1948

THE annual meeting of the Council was called to order by the president, Dr Edward P Bagg, on Monday, May 24, 1948, at 7 00 p m , in the Georgian Room of the Hotel Statler, Boston

Two hundred and thirty-five councilors were present (Appendix No 1)

After opening the meeting, the President read the following obituaries

**GEORGE JAMES CONNOR**—Another fellow-councilor, Dr George J Connor, a leading citizen of Haverhill, has passed on since our last meeting Trained at Holy Cross, Tufts and the Maryland Medical College, he elected to serve his city on the Board of Health and in the direction of municipal hospitals For twenty-five years he served on the board and held the chairmanship at the time of his death

His main clinical leanings, however, were surgical, particularly in the field of industrial medicine He was a visiting surgeon to the Hale Hospital and a member of the advisory board for more than fifteen years

Dr Connor represented the Essex North District Medical Society on the Council and was a member of the Committee on Industrial Health Likewise, he was a fellow of the American Association of Industrial Physicians and Surgeons

A witty, cheerful soul, quick to make friends, whom he kept, he will be sadly missed in his home and in his civic and medical associations We pay tribute to George Connor, the able physician, for his natural flair for public relations and for his willingness to work for the elimination of health hazards whether industrial or general

**ISAAC S F DODD**—In March, 1930, sixty physicians of central and southern Berkshire arranged a dinner in celebration of the fortieth anniversary of the medical practice of a brisk little man with angular features but not much hair, who was wont to pucker up his lips and whistle as he walked The warmth of the tributes paid to Isaac S F Dodd by his colleagues showed clearly enough that such limitations were purely physical

"In the years I have known him," wrote one of the diners, "he has done more for the young men than any other man in this community He was a lover of the clean life and a great reader of good books His quizzes while operating were outstanding and as peculiarly his own as his whistle Many Berkshire men have had cause to be thankful to him for his advice and teaching"

The Massachusetts Medical Society also acknowledged a debt to Isaac Dodd for his professional attainments and for years of faithful service in the Council by honoring him with the office of vice-president in 1946-1947 Quite in keeping with his character, he stood ready without a moment's hesitation to take over the intricate task of running the annual meeting of the Society when illness threatened to incapacitate President O'Hara last May "Just tell me what there is to do," was all he said

Dr Dodd was equally ready to serve his country in World War I, attaining the rank of captain in the Medical Corps Chief of the Surgical Service at Pittsfield's House of Mercy, he was also an attending staff surgeon at St. Luke's In his turn, he directed the destinies of the Berkshire District Medical Society The American College of Surgeons also elected him to fellowship in due course

Here was a minister's son who made good Indeed, he made good for more than three quarters of a century

after his auspicious arrival in a Presbyterian mission in Hanglow, China New York University numbered him among her high-honor graduates, but most of his clinical ability was developed at first hand with unremitting application to the needs of his patients in general practice

Early in February, 1948, physicians once more gathered in the Berkshire District to pay a final tribute to their friend and mentor, Isaac S F Dodd May we join our hopes to theirs that honor and esteem will follow him in whatever Elysian field he shall be assigned hereafter to serve

**EDWARD JOSEPH O'BRIEN, JR.**—Back in 1933, one of the ablest of all football referees in this or any other country, Dr Edward J O'Brien, Jr, turned in his whistle and folded away the famous white knickers that he had established as a familiar feature of games big and little throughout the land The decision was not easy, but finally he came to agree that medicine is truly a jealous mistress

To the game he had loved, he owed much Not only did it build him a nationwide esteem but also fees he earned by officiating enabled him to train himself at Tufts for a medical career, after earlier preparation at the Boston Latin School and Boston College On his merits he rose to the position of surgeon-in-chief at the Cambridge City Hospital For nearly thirty years he served as urologist to St. Elizabeth's Hospital He was sought also as a consultant in urology at many greater Boston institutions Besides serving on the Council as a representative of Middlesex South District Medical Society, Dr O'Brien was a fellow of the American College of Surgeons and the American Urological Association and a member of the American Board of Urology

On February 16, 1948, the game of life came to an end for our distinguished fellow councilor, who was in there working hard as usual until the final whistle Of the passing of Dr Eddie O'Brien, his good friend Bill Cunningham wrote, in the *Boston Herald* for February 16, 1948 "The shock was tough and personal just as it will be for thousands of others who knew and loved the little guy and yet, I thought, why mourn? What more could a man do with his life? Live a little longer, maybe, but he couldn't live any better"

Dr O'Brien was the father of four fine sons, who all distinguished themselves and fortunately survived active and hazardous war service, and of a beautiful daughter Each must have drawn a full share of inspiration from this yule soul, who brought honest satisfaction to so many contestants and understanding sympathy to those in need, whether on the gridiron, the operating table or in his home.

And so should we be inspired by his example, which speaks so much louder than words

**FREDERICK REIS**—On February 4, 1948, Dr Frederick Reis, another long-time member of the Council, died at his home in Jamaica Plain at the age of seventy-two Besides his service on the Council, he handled the funds of the Norfolk District Medical Society for ten years as treasurer

His friends speak of him as a kindly, companionable person, and say that his passing will be keenly felt, particularly by his students, past and present Born in Boston, Dr Reis was also educated in Boston schools, graduating from Tufts College Medical School in 1903 The greater part of his professional accomplishment was achieved in the same school in the Department of Chemis-

try, where he served as professor for more than a quarter of a century

It should be remembered that he was alert to changes that arose during his lifetime and that his interest in the affairs of the Society was always keen, since the day he was elected to the Council in 1922

It is fitting, therefore, to pay tribute to this man for all that he has contributed to fellow members and to his fellow men through the many students that he had a hand in training

At the request of the President, the Council stood in silent tribute to the departed members

The President then announced the following interim appointments, which were confirmed by vote of the Council

**To the Council**

Arthur W Allen, Suffolk, to replace Wyman Richardson (resigned)

Arnold P George, Essex North, to replace George Connor (deceased)

**To the Committee on Emergency Medical Service**

Reginald Fitz, *Chairman*, Suffolk

Charles H Bradford, Suffolk

Donald E Currier, Essex South

Eugene C Eppinger, Norfolk

J Roswell Gallagher, Essex North

Allen S Johnson, Hampden

Thomas H Lanman, Suffolk

Edward D Churchill, Middlesex South (in consulting capacity)

**To the Committee on Benevolence**

Dwight O'Hara, *Chairman*

Theodore L Badger

Robert W Buck

Eliot Hubbard, Jr

Charles C Lund

**To the Advisory Committee to the Red Cross Blood Bank**

John F Conlin, *Chairman*

F Harold Allen, Jr

William B Castle

Stephen Brown

William P Murphy

Joseph E Ross

C Stuart Welch

**To the Committee on Postgraduate Assembly**

John F Conlin

**To the Massachusetts Central Health Council**

Paul Nathan, Holyoke

Merrill E Champion, Boston

Earle M Chapman, Boston

**To the Committee to Meet with the Massachusetts Hospital Association**

Leland S McKittick

The Secretary presented the record of the meeting of the Council of February 4, 1948, as published in the *New England Journal of Medicine*, issue of April 8, 1948, and moved its acceptance. The motion was seconded and so voted.

The Secretary stated that it had been noted that the minutes of the Executive Committee meeting of January 7, 1948, had not been approved at the Council meeting on February 4, 1948, and moved that they be accepted. The motion was seconded and so voted.

The Secretary then moved the acceptance of the minutes of the Executive Committee meeting of

April 7, 1948, as distributed in the Circular of Advance Information for this meeting. The motion was seconded and so voted by the Council.

**REPORT OF THE TREASURER**

Dr Eliot Hubbard, Jr, Middlesex South, moved the acceptance of this report (Appendix No 2). This motion was seconded and so voted by the Council.

**REPORTS OF COMMITTEES**

*Executive Committee*—Dr H Quimby Gallupe, Middlesex South, *Secretary*

The Secretary submitted the report of the meeting of April 7, 1948, as circulated in mimeographed form (Appendix No 3) and moved its acceptance. The motion was seconded, and it was so ordered by vote of the Council.

*Committee on Nominations*—Dr Albert A Hornor, Suffolk, *Chairman*

The committee had convened at 8 Fenway, Boston, on April 7, 1948, and had nominated the following officers of the Society for the year 1948-1949

President, Dr Daniel B Reardon

President-elect, Dr Arthur W Allen

Vice-president, Dr Donald Munro

Secretary, Dr H Quimby Gallupe

Treasurer, Dr Eliot Hubbard, Jr

Assistant treasurer, Dr Norman A Welch

Orator, Dr C Sidney Burwell

These nominations were unanimous, and Dr Hornor moved the acceptance of the report.

The motion was seconded, and it was so voted.

Dr Bagg asked for any further nominations. There was no response, so that Dr Hornor moved that the nominations be closed. The motion was seconded and carried.

Dr Hornor moved that the Secretary cast one ballot for the list of nominees as presented. The motion was seconded and so voted.

The Secretary cast one ballot as directed. Dr Bagg then introduced Dr Daniel B Reardon as follows:

The man chosen as president has been a member of the Society for a good many years. He first joined in 1905. He attended the Lawrence Scientific School at Harvard and got his medical degree from the same university in 1903. And he served as surgical house officer in the Boston City Hospital. Then he retired to Quincy forty-three years ago. He has been there ever since, which shows that he must amount to something. As a matter of fact, he has been visiting surgeon at the Quincy Hospital for thirty-seven years, and on the consulting staff for the past three years. And for twenty years he has been a member of the American College of Surgeons. For twelve months we have worked hard preparing him for the duties that lie ahead. I can assure you that he has been faithful in his attendance, and promises to make you an excellent presiding officer.

He has a much more eloquent method of speech than mine, so that you will probably understand what is going

on for the next year, and your parliamentary problems will be absent. I take great pleasure in introducing your next President

Dr Reardon replied with an address, which was published in the June 10 issue of the *Journal*

Dr Bagg then said that Dr Arthur W Allen could not be present because he was attending the meeting of the American College of Surgeons in Canada Drs Donald Munro and H Quimby Gallupe were then introduced

*Committee on Public Relations* — Dr Harold R Kurth, Essex North, *Secretary*

President Bagg stated that the report of the committee (Appendix No 4) was largely informational He hoped that the fees of the Blue Shield could be increased before long but believed that this could not be done until the financial reports warranted it He stated that the committee voted to discharge the subcommittee on Blue Shield and Blue Cross and to refer future questions to the Executive Committee, inasmuch as that committee was the incorporator of the Blue Shield He asked for Council approval of that action Dr Elmer S Bagnall, Essex North, so moved The President then said that with Dr Bagnall's permission he would word the motion that the President would appoint a subcommittee of the Executive Committee to oversee the Blue Cross and Blue Shield problems Dr Bagnall gave his permission, and the motion was seconded and so voted

The President then said that Dr Hagler's committee had decided that the best way to correct difficulties arising from failure of doctors answering calls was to refer the matter for solution to the district societies The Public Relations Committee approved this recommendation

Dr Bagg asked for approval of this recommendation by the Council It was so moved The motion was seconded, and it was so voted

The President asked for approval of his action in appointing representatives of the Massachusetts Medical Society to a council for the study of voluntary hospital costs (he had appointed Drs Gallupe and John Spellman) This approval was moved by Dr Richard M Smith (Suffolk), and the motion was seconded and so voted

The President described the amount of work done by Dr John F Conlin and stated that the committee had approved the employment of an assistant, the cost to be met out of his supplementary budget

Dr Bagg asked for Council approval of this action A motion was made to approve the action It was seconded and so voted

Dr Bagnall moved the acceptance of the report. The motion was seconded, and it was so voted

*Committee on Legislation* — Dr George R Dunlop, Worcester, *Chairman*

The report of this committee (Appendix No 5) was presented by Dr Dunlop, who stated that he wished to make an informational supplementary report important enough to bring to the attention of the Council Dr Dunlop mentioned the proposed draft law being considered by Congress, which has specified a special call for physicians up to forty-five years of age The committee believed that this was a reflection on the patriotism of doctors, and had sent telegrams to congressmen opposing such legislation

He pointed out that Governor Warren, a candidate for nomination for President, had come out for compulsory health insurance He said that telegrams had been sent to all Republican delegates from Massachusetts to oppose any such plank in their platform Dr Dunlop said he would like to have Dr Bagnall report on the National Health Assembly held in Washington May 4, 1948

Dr Bagnall described the work of the Assembly and quoted from editorials in the *Journal of the American Medical Association* and ended by saying that the nation seemed to be on the way toward development of a plan for the production and distribution of medical services suitable to the American form of democracy

Dr Bagg suggested that the Council applaud Dr Bagnall's efforts and report (Applause) Dr Dunlop moved the acceptance of both reports The motion was seconded and so voted

*Committee on Publications* — Dr Richard M Smith, Suffolk, *Chairman*

The report of the committee (Appendix No 6) was presented by the Chairman

Dr Smith exhibited a chart showing the growth of the *Journal* during Dr Robert Nye's administration from 1936-1947 Dr Smith moved the acceptance of the report The motion was seconded

Dr Bagg pointed out that the circulation in ten years had jumped from 6,131 to 25,001, and the expenses from \$58,000 to \$240,000 In 1937 the *Journal* cost each fellow \$4.00 In the last three years there has been only income for the Society, but the future might not be so bright because expenses are still mounting

The motion to accept the report was unanimously carried

*Committee on Ethics and Discipline* — Dr Ralph R Stratton, Middlesex East, *Chairman*

Dr Stratton, after drawing attention to the last paragraph of the report (Appendix No 7) and stating that the report was purely informational, moved its acceptance The motion was seconded and so voted Dr Bagg then thanked Dr Stratton and his committee for their efforts in behalf of the Society

*Committee on Membership* — Dr Peirce H Leavitt, Plymouth, *Chairman*

In the absence of the Chairman, Dr Bagg asked the Secretary to read a supplementary report of the Committee on Membership as follows

During a meeting of the Committee, held on Monday, May 24, the name of Sir Reginald Watson-Jones, visiting orthopedic surgeon to His Majesty, King George VI, was presented to the Committee for action by the President and the Secretary. The Committee unanimously approved of this nomination for honorary fellowship and refers it for final decision to the fellows assembled at the annual meeting, as permitted by Article II of the by-laws

A motion to approve the action of the committee subject to the vote of the annual meeting of the Society on May 25, 1948, was made, seconded and carried. The Secretary then moved that the Council grant the honorary fellowship subject to the vote of the Society. The motion was seconded and carried

*Committee on Public Health* — Dr Roy J Ward, Worcester, *Chairman*

In the absence of the chairman, Dr Bagg asked Dr Conrad Wesselhoeft (Suffolk) to present the report (Appendix No 7)

Dr Wesselhoeft moved the acceptance of the report. The motion was seconded

Dr Frank B Carr addressed the Council as follows

In this very difficult era, we are all cognizant of the need for reliable statistics regarding the epidemiology of heart disease. Mortality figures in this disease have made it imperative for the American Heart Association and the United States Public Health Service to do something about it

The United States Public Health Service offers to make an epidemiologic study, and the New England Heart Association naturally offers its support to such an investigation

There are, however, certain queries that arise in the minds of some of the Worcester councilors

How complete and comprehensive is this study to be? The diagnosis of heart disease may be as simple as the application of a stethoscope by one qualified to hear. It may depend merely on the proper evaluation of symptoms of precordial pain, which requires no great experience. Or the diagnosis of heart diseases in certain cases may become quite an elaborate procedure, requiring electrocardiograms, x-ray films, fluoroscopy, determinations of blood chemistry and basal metabolism and so forth. There is no one simple system applicable to all cases, as in the diagnosis of diabetes

Before supporting a federal survey of the epidemiology of such a complex condition as heart disease, we should want to be informed about how complete the study would be. We should want to be assured of the validity of the diagnosis established, and we should like to know how much such a project is going to cost.

In the diabetic survey in the town of Oxford, it has been estimated by some, although not officially expressed, that the cost was about \$1,000 apiece for the discovery of some 25 cases of diabetes

The diagnosis of heart disease is a much more complicated problem. The setup would have to be infinitely more elaborate and expensive, and we wonder if the results ascertained would be of the value we might hope

We do not like investigations for the sake of investigation. We want to be assured that the methods used will be scientifically sound, and that the statistics derived

from such a study will be of general value sufficient to warrant the expenditure of what will be a considerable amount of money

Dr Bagg thanked Dr Carr and asked for a vote on the motion of acceptance of the report. It was so voted

Dr Bagg then asked Dr Wesselhoeft if he wished to move the adoption of the committee's endorsement of the cardiac surveys in Newton and Framingham. Dr Wesselhoeft replied as follows

This study has been requested by Newton, and I understand that arrangements have been completed with Framingham Union Hospital. This study is to be made by the Massachusetts Department of Public Health, Harvard Medical School and the United States Public Health Service

It is supported by the Commissioner, and it has the approval of the New England Heart Association. It seems to me that any such investigation carried out under such auspices would be carried out thoroughly and well

Dr Wesselhoeft moved the endorsement of the program, which had been recommended by the committee. Dr Richard M Smith seconded the motion. In discussion Dr Vlado A Getting, Middlesex South, spoke as follows

This study will be composed of two phases. The phase to be carried out in Newton is entirely an educational program, designed to convince patients to seek medical advice if they suspect that they have heart disease, and to seek periodic examinations

The project at Framingham is the development of case finding procedures and will be carried on by cardiologists who are actually employed by the Public Health Service and by men practicing in the community and in the surrounding communities

In each instance of this project Public Health Service personnel are lent to the Massachusetts Department of Public Health and by the Department of Public Health to the city of Newton and to Framingham, being under the direction, while working in those communities, of the local boards of health

The staffs of the Newton-Wellesley Hospital and of the Framingham Hospital are thoroughly acquainted with each of these projects and have given their approval, as have advisory committees. An advisory committee on this project, consisting of many cardiologists and including representatives not only from the Society but also from medical schools and schools of public health and from the Department of Public Health, have carefully reviewed these projects

We are trying to do two things to determine, as early as possible, which persons may develop heart disease, and to bring them under the attention of physicians

It seems that if we can discover cases early, before actual clinical onset, the patients will have a more useful and productive life and will be able to continue to be supporting citizens in the community, rather than incapacitated, perhaps disabled in some way, and thus a burden upon their families and the communities

The two projects — one case finding, and the other educational — are companion projects. We are not going to give any medical care in either project.

The physical examinations and the electrocardiograms and other studies will be carried on in Framingham by expert cardiologists employed by the Public Health Service, under the direction of the local board of health, and will be selected only with the advice of the New England Heart Association

I want to assure the councilors of Worcester (of which I had the honor of being a member some time ago) and I had the honor of being a member some time ago) and the entire Society that there is nothing in this program that smacks of either state or socialized medicine. We

are not contemplating medical care. This is nothing more than case finding and education.

If these programs succeed, it will enable the general practitioner and the cardiologist to be of greater service to their patients.

Dr. Bagg then called for a vote, and the motion was carried after a show of hands and a count by the Secretary. Dr. Wesselhoft moved acceptance of the committee report. The motion was seconded and so voted.

*Committee on Medical Defense*—Dr. Horatio Rogers, Suffolk, *Chairman*

Dr. Rogers stated that as of January 1, 1948, there were 9 cases of malpractice pending. One case was disposed of during 1947. Total bills for legal services and legal disbursements for 1947 were \$1474.51. There were no other expenses.

Dr. Rogers moved acceptance of the report. It was seconded and so voted.

*Committee on Finance*—Dr. Robert W. Buck, Middlesex South, *Chairman*

Dr. Buck said that the committee had met on April 28, 1948, to discuss the problems arising from a change in classification of the Society by the Treasury Department from 101 (6) to 101 (7) and that this change made the Society liable for Social Security taxation. The committee authorized the Treasurer to assume 50 per cent of the tax burden of the *Journal*. Gifts to the Society were discussed because that might in the future make the Society liable for income tax. The committee recommended that all gifts be accepted with the condition that they be used only for clearly scientific, educational, charitable and literary purposes.

The committee also recommended that the salary of Miss Barbara Adler be raised from \$35 to \$40 a week beginning July 1, 1948.

Dr. Buck moved the acceptance of the report. It was seconded and carried.

A motion was then made to suspend the rules. This motion was seconded and so voted.

Dr. Buck moved that the Council approve the payment of the tax. The motion was seconded. Dr. Hubbard then told about other states in which the tax was paid. The motion was put to vote and carried. A motion to approve payment of 50 per cent of the *Journal* tax was made, seconded and so voted. Dr. Buck made a motion to approve the committee recommendation concerning the use of moneys received in the form of gifts. This motion was seconded. After much discussion a motion was made to refer the matter to the Executive Committee. This was seconded and so voted. Dr. Buck's motion was then voted and carried. Dr. Bagg then asked for an approval of Miss Adler's salary increase, and this was given unanimously.

Dr. John E. Moran, Franklin, moved that the Council instruct the Executive Committee that it

is not in favor of accepting any gifts as described in the report of the Committee on Finance. This motion was seconded. Dr. Bagg called for a vote. The Secretary declared a tie. Dr. Bagg voted in favor, and the motion was carried.

A motion was made to end the suspension of rules. This was seconded and so voted.

*Committee on Society Headquarters*—Dr. Frank R. Ober, Suffolk, *Chairman*

The chairman stated that the Committee on Society Headquarters had made no progress in its efforts to make more room for the Massachusetts Medical Society. The Committee was still working on this problem, which has proved to be a difficult one.

The Secretary moved its acceptance. The motion was seconded and so voted.

*Committee on Industrial Health*—Dr. Daniel L. Lynch, Norfolk, *Chairman*

Dr. Lynch presented the report of the Committee (Appendix No. 9) and moved its acceptance. This motion was seconded and carried.

*Committee to Consider Expert Testimony*—Dr. Francis P. McCarthy, Norfolk, *Chairman*

The original committee of five members was appointed by the President in 1936, to consider expert medical testimony.

After failing to function, a revision of the membership was made in 1942 and again in 1947. The last committee report was laid on the table, and the present committee submitted its report for consideration by the Council.

The present Committee met and discussed all phases of the subject of medicolegal testimony, including ordinary as well as expert testimony.

The Committee, with members of the Massachusetts Judiciary and Bar and the chairman of the Committee on Ethics and Discipline and Board of Registration in Medicine met and agreed on the importance of having a functioning committee deal with medicolegal testimony and problems.

The states of Minnesota and California have established permanent committees on medical testimony, and reports indicate that these committees are functioning well.

The Committee, together with the chairman of the Committee on Ethics and Discipline and the Board of Registration in Medicine, as well as members of the legal profession, agreed that a group of so-called "listeners" should be appointed to serve when requested, to check on medical testimony.

It was agreed that the presence of a "listener" in court would definitely act as a deterrent in controlling medical testimony and serve to make the medical witness more cautious and docile in his testimony.

A panel system of choosing representatives of the Society who are specialists in their various fields to testify as experts was discussed, but no conclusion was arrived at, that could be considered satisfactory under the present legal statutes.

All the members of the Committee, together with those consulted, agreed that the Committee should be a standing one and collaborate with the Committee on Ethics and Discipline and the Committee on Medical Defense. The Committee would act as a clearing house for all cases in which ordinary or expert medicolegal testimony was concerned.

It was proposed that the by-laws of the Society be amended to the effect that a standing committee be appointed annually by the President, to be known as the Committee on Medico-Legal Testimony.

That the duties of this committee be educational on medicolegal matters, and that it collaborate with the legal profession and concern itself in the investigation of all questions relative to medicolegal testimony that may be considered irregular by the complainants.

Dr McCarthy moved the acceptance of the report. The motion was seconded and so voted.

Dr McCarthy then stated that the report contained a recommendation for a proposed amendment to the by-laws of the Society providing for a standing committee appointed annually by the President to be known as the Committee on Medico-Legal Testimony, that the duties of the committee be educational on medicolegal matters, and that it collaborate with the legal profession and concern itself in the investigation of all questions concerning medicolegal testimony that might be considered irregular by the complainants.

Dr Bagg suggested that the request might be referred to the Executive Committee. The motion was seconded.

Dr McCarthy then moved that the committee be discharged. The motion was seconded and so voted.

Dr Donald Munro, Suffolk, asked if he might discuss the report. President Bagg said that the report had been accepted and was open for discussion. Dr Munro stated that he believed the use of the word "listeners" might embarrass the Society.

Dr Carl Bearse, Norfolk, said that the Committee on Malpractice Insurance had discussed the subject and believed the whole subject in all aspects should be studied.

Dr Vlado Getting, Middlesex South, rising to a point of order said that the motion was for acceptance of the report. No motion had been made recommending "listeners."

Dr Bagg agreed with Dr Getting and called for a vote on the motion. It was so voted.

### *Committee to Meet with the Massachusetts Hospital Association — Dr Albert E Parkhurst, Essex South, Chairman*

The Committee, to which the Council had assigned the duty of negotiating with the Hospital Association regarding its approval of the principles proposed by the Committee appointed to study special services, had held two meetings.

At its first meeting, on February 25, 1948, which was attended by Drs Bagg, Reardon and Gallupe, in addition to the members of the Committee, there was a general discussion of principles recommended by the Committee appointed to define and study hospital services and medical services, and to establish proper relations between physicians and hospitals, which were approved by the Council at its October meeting. It seemed highly desirable that this conference with the Hospital Association be held before its annual meeting scheduled for March 15, and a date (March 3) was arranged through Dr Norbert A Wilhelm, chairman of its Committee on Professional Services, this problem having been assigned by the Massachusetts Hospital Association.

At this conference, the Society was represented by Drs Bagg and Gallupe and four members of the Committee. Representing the Hospital Association was Dr Wilhelm, of the Peter Bent Brigham Hospital, as chairman, and Mr Warren Cook, of the New England Deaconess Hospital. The third member of the Committee, Miss Amy Birge, of the Cooley Dickinson Hospital, in Northampton, was unable to attend because of illness.

Arguments about why these principles should be approved by the Hospital Association were presented, chiefly by Drs Bagg and McKittrick. Dr Wilhelm stated that his committee had met the day previously and had voted that "no action be taken at this time." Their decision was based chiefly upon their belief of the uncertainty whether the Blue Cross could continue to provide adequate prepaid hospital insurance. As hospital administrators they believed its successful operation was essential to the welfare of hospitals, and they refused to approve anything they thought might further embarrass it. They also said that because of poor public relations on the part of the hospitals, a more complicated system of billing hospital costs to the patient would be too confusing and undesirable to be undertaken. Incidentally, they stated they believed that very few hospitals had a system of accounting sufficiently comprehensive to be able to work out all details of cost accounting that would be necessary under this plan.

There was a great deal of discussion during which the representatives of the Society tried unsuccessfully to convert the representatives of the Association to its point of view. They were unwilling to grant their approval of these principles.

even though the Society agreed to the postponement of their adoption until a later date because they believed that in these days when the Blue Cross and so many hospitals are in great financial distress, the whole question of voluntary hospital service is at stake. They insisted that now was not the time to undertake the adoption of these principles. Although the Committee believed in the fairness of these principles and urged their adoption, it was believed that the representatives of the Association were sincere in their point of view. As a result of this conference, it was believed that nothing more could be done at present.

Dr Parkhurst moved the acceptance of this informational report. The motion was seconded, and it was so voted.

Dr A J A Campbell (Suffolk) moved that the committee continue its efforts along the same lines and report to the Council. This motion was seconded and so voted. Dr Bagg asked Dr Daniel B Reardon if he had appointed the same committee and Dr Reardon said he had.

The motion was put to a vote and carried unanimously.

#### *Committee on Postgraduate Medical Education— Dr W Richard Ohler, Norfolk, Chairman*

The report of the Committee was as follows:

##### *Brief Outline of Present Plan of Postgraduate Teaching*

The present concept of postgraduate medical education as conducted by the Massachusetts Medical Society is to provide such teaching to all physicians in the Commonwealth, without charge, to divide the Commonwealth into teaching districts and to provide to each district such programs as are selected by the local committee, to serve the Greater Boston area and such other areas as can participate with a series of exercises given at Sanders Theater, in addition to the Greater Boston area, the other teaching areas are as follows:

- Number 1 Pittsfield-North Adams District
- Number 2 Springfield-Holyoke-Northampton-Greenfield District
- Number 3 Worcester District
- Number 4 North Shore District
- Number 5 Haverhill-Fall River-New Bedford District
- Number 6 Plymouth District (this District is new for 1947-1948)
- Number 7 Lowell-Haverhill-Lawrence-Newburyport District

##### *Results of This Year's Activities*

During the year 1947-1948, a total of 27 exercises has been given in the outlying districts. The total registration for the Sanders Theater program was 1101 at the date of this report.

Thirteen hundred and sixty-eight replies were received to a postcard questionnaire, 735 of those replying had not attended last year's exercises, 1322 believed that the exercises should be continued, 905 of those who replied were fellows of the Society. It is of interest that the 463 physicians who are not Society members represent a third of the total number of replies received and constitute a much larger proportion of those who have registered for the exercises.

It is not necessary to remind the Council about weather conditions during the late fall and winter season. Despite all sorts of difficulties, instructors have been very co-operative, and attendance has been excellent. On the basis of general interest, therefore, your committee can

report that the district programs have been a success. And, so far as the Sanders Theater program is concerned, the large registration speaks for itself.

##### *Suggestions for Future*

Your committee believes that the Massachusetts Medical Society should continue a program of postgraduate medical instruction and that this program should be open to all physicians in the Commonwealth without charge. We also believe that the Sanders Theater exercises should be continued.

The method of conducting exercises in the districts apart from Greater Boston is open to discussion. The whole conception of postgraduate teaching in the past three years has been to break away from the district geographical limits. The reason for this has been to attract physicians who are not members of any district. In other words, the intent of this program has been to attract all physicians, whether or not they are members of any district society.

This idea may be all right in theory, but it does bring up certain practical difficulties. For example, certain teaching centers have morning and afternoon programs and others evening programs, and, needless to say, all want evening programs. In addition, the present plan does throw quite a transportation burden on the instructing teams, especially in certain districts. All this could be settled if we planned our programs on the basis of the geographical limits of the various district societies. However, there are certain practical difficulties to this idea. First, your committee doubts that the district-society idea would attract physicians who are not members of any District Society, and, incidentally, it is this group that we are eager to reach. Second, such a change would involve an increase in the budget.

##### *Conclusion*

Despite the fact that the present idea involves certain local complications as well as a certain amount of stress and strain on the instructing teams, your committee believes that to keep the budget within certain limits and to make the greatest appeal to physicians not members of any society, it is desirable to continue with the present plan. In making this recommendation, it is understood that the committee can work still harder in building up proper local co-operation.

Dr Ohler stated that the report was purely informational, and noted that the registration at Sanders Theater was 1101, the total being 1400, and that 7400 doctors were in attendance during the course. The average was 400. Dr Ohler moved the acceptance of the report. The motion was seconded. Dr Bagg pointed out the excellence of the report and that more than half the doctors in attendance were from substandard schools. The motion was put to vote and carried unanimously.

Dr Ohler moved that the recommendation to continue the program in 1948-1949 as in 1947-1948 be approved. The motion was seconded and so voted.

#### *Committee on Medical Economics—Dr Leland S McKittrick, Suffolk, Chairman*

The report, which was presented by the chairman, was as follows:

The Committee met on March 10. Drs Elmer S Bagnall, and Allan M Butler, of the committee, President Edward P Bagg, President-Elect Daniel B Reardon and the Secretary were present.

The objectives of the National Physicians' Committee are defined in a recent communication as follows:

In the public interest to preserve, in the United States, our system of private medical practice

Familiarizing the public with the facts in connection with the values, the methods and the achievements of American Medicine.

To aid in the development of plans and to encourage the utilization of facilities that will result in the most widespread distribution of the most effective medical care and surgery

The Committee voted to approve the objectives of the National Physicians' Committee but disapproved some of the methods employed

Dr McKittrick moved acceptance of the report. The motion was seconded. Dr Bagg said that he had had a letter from Dr Allan M Butler, of the Committee, stating that he wished to change his vote and withdraw his approval.

Dr Bagnall said that Dr Butler's letter was not pertinent because surely the committee could not assume any responsibility for anything the National Physicians Committee did.

Dr McKittrick added that the subject of changing or attempting to change the policies of the National Physicians Committee had not been discussed.

Dr Bagg called for a vote, and the motion was passed. He assured Dr McKittrick that the subject was closed.

Dr Bagg then asked for final approval of the changes in the by-laws as printed and noted two errors in the use of "Inc" after Massachusetts Medical Service in the first paragraph.

Dr Barse then pointed out that Chapter 4, Section 1, as amended, did not include the vice-president of the Society. Dr Bagg thanked Dr Barse and called for a vote accepting the amended by-laws. The motion was carried.

*Committee on Physical Medicine*—Dr Arthur L Watkins, Middlesex South, *Chairman*

No new business had been referred to the Committee.

The American Board of Physical Medicine, Inc., had been approved by the Advisory Board for Medical Specialties and the first examinations had been conducted in Minneapolis in September, 1947, approximately 100 physicians had been certified to date.

An annual review of physical medicine was prepared for publication in the Medical Progress section of the *New England Journal of Medicine* entitled "Technical Advances in Physical Medicine."

*Committee to Make Recommendations for Directors of the Blue Shield*—Dr Leland S McKittrick, Suffolk, *Chairman*

The Committee submitted the names of the following men

To hold office until 1949

Mr Eben H Ellison, Jr, Proctor Ellison Co, 26 South Street, Boston, to replace Mr Hugh Nawn

Mr Joseph K Milliken, Jr, reappointment.

Dr Samuel A Robbins, reappointment.

Dr James C McCann, reappointment.

Mr Harold B Leland, reappointment

To hold office until 1950

Mr Philip Morgan, reappointment

Dr Norman Welch, reappointment

Dr Arthur W Allen, reappointment

Mr J H Humphrey, reappointment

Mr Roswell Phelps, reappointment

To hold office until 1951

Mr Benjamin Hull, Department of Labor and Industries, State House, Boston, to replace

Mr Ernest Johnson

Mr Thomas G Brown, reappointment.

Dr Elmer S Bagnall, reappointment.

Mr Daniel J Boyle, reappointment

Dr Eugene Walker, reappointment.

Dr McKittrick moved the adoption of the report and it was seconded. Dr Bagg asked if there were any other nominations. There being none, the motion was put to vote and carried.

*Committee on Veterans Affairs*—Dr G Philip Grabfield, Norfolk, *Chairman*

The Committee on Veterans Affairs had held no meetings since its reappointment at the annual meeting in 1947. It was understood at that time that the Committee would not meet unless something arose that required its consideration or unless some individual or corporate body brought some subject to it for consideration. If no matters requiring consideration came up by the time of the Annual Meeting in 1948 it was the opinion of the committee that it should be discharged.

Dr Grabfield was not present, and Dr Bagg noted that the committee asked to be discharged. Dr Albert A Hornor, Suffolk, moved acceptance of the report. The motion was seconded.

Dr Lewis S Pilcher (Middlesex South) spoke as follows

Gentlemen, there is just one point I think should be brought out before we proceed to accept the discharge of the Committee. There is a group of younger veterans in the Society who have been quite dissatisfied with the Society's interest in veterans' affairs.

I am quite certain that if the Society discharges the Committee on Veterans Affairs, these veterans will form their own organization outside the Society, and take over the interest in veterans' affairs that previously had been the province of the Society.

This matter was discussed at the annual meeting in 1947. At that time representatives of the Society and of the Veterans' Committee very strongly opposed the formation of a Veterans' Medical Society outside the Massachusetts Medical Society, and promised the veterans who were present that the Society would adequately represent their interests and would take whatever action was necessary to rule out any complaints they might have, and to make adjustments that were necessary.

I do not know whether there is any need for such action or not, but obviously the Committee has taken no action and has taken no initiative. As the report states,

it was their understanding that nothing was to be done unless complaint was made.

I have no recommendation to make, one way or the other, except to mention the fact that if we discharge the Committee on Veterans Affairs, I know that the veterans will organize a society of their own outside the Massachusetts Medical Society.

They have already had their organizational meeting, and another meeting is, I believe, to be held tomorrow morning at the Copley Plaza Hotel.

I should be grateful if some of the men who are very familiar with veterans' affairs and medical circles would state what they feel, and whether we could accept the discharge of this committee, whether we should appoint a more active committee, or whether we should leave things to a veterans' society outside the Massachusetts Medical Society.

Dr Bagg replied as follows

Thank you for bringing up that matter. We were entirely ignorant of such a situation, because no reports had come to us at all, and there were no items to refer to Dr Grahfield's committee.

I will say this when I was getting together the list of committees last year, this committee seemed to be a very cumbersome one, and I have a feeling that a smaller committee, perhaps more actively made up of veterans themselves, might function better.

Therefore, the only way out of this situation that I can see is to refuse to discharge the committee, and then have a subsequent motion that the Committee be re-organized on the lines laid down.

Dr Bagnall then spoke as follows "It occurs to me that one way out of this would be to have this committee resign and let the president-elect, who will be the next president, appoint an appropriate committee, and that will take care of it all right."

Dr Bagg considered that a good suggestion. He stated that some definite information should be obtained from the veterans, adding that if the Society asked them for suggestions for appointments, that might solve the difficulty.

Dr John J. Curley, Worcester North, then spoke as follows

Last year the veterans met downstairs here, and we were promised that we would have either a section or some sort of committee within the Society that would be representative of the veteran physicians. This committee was appointed, and I know that one man in each district was appointed as a member of the committee, but to my knowledge, the man in my district was never asked to go to a meeting. So that whether the committee ever met or not, I do not know.

But the veterans, especially the veterans of World War II, who are physicians are especially desirous of having some section within the Massachusetts Medical Society. Whether it be a separate section or a separate society is up to the Society. But as we understood last year, the veterans were to have a committee and were to be allowed to form some sort of section within the Society, and to date nothing has been done about it.

Whether we need a new committee or whether we need some different type of committee or not, is the question.

But I can speak on behalf of the fellows who are councilors and who would make good live wires. I can think of a few men who could get this thing organized so there would not have to be any separate society within the state of Massachusetts.

A postcard notice has been sent out that there will be a meeting tomorrow. I should like to suggest to the President that he appoint somebody to go to that meeting

and speak for the Massachusetts Medical Society, as Dr Pilcher and I did last year at the meeting downstairs. And I think Dr Pilcher would be a very good one to send.

Dr John F. Conlin, Suffolk, spoke as follows

The matter of forming a new group is a matter that has been discussed quite a bit around the Commonwealth, and as long as it is this far on the agenda, I should like to rise to the point, although I am not a voting member of the Council. The chief argument that is put forth for organizing a veterans' group of World War II physicians is that they would be in a position to carry veterans' organizations along with them in the event that a matter such as compulsory national health insurance or something came up.

Whether that is enough to warrant a complete society or not, I hold in very serious doubt. I believe that just as much and just as effective work can be done by physicians working in existing veterans' organizations as members of those organizations, and spreading the word, whatever it may be.

Along that line, I believe very strongly, after covering the state, — and the things I say here I hope to say at the meeting at 10 o'clock on Wednesday when the World War II physicians are in meeting, — that one of the greatest dangers in medicine right now is this tangle system of the successive groups that will grow up.

It has been said very well in recent days that first all the members of one specialty get together and form a society, then a college is formed within that society, and then an academy within that society, and then perhaps a board. And then there are multiple specialty groups. And in this monstrous growth we are losing sight of the distinct medical societies and the local groups that (and I do not think it needs any urging with this group) are the basis of our entire medical structure.

They come first and are the thing we are most interested in. The Society is based on district societies and the national organization is based on state societies. Consequently, unless a very definite need exists, we should not multiply societies.

There is an organization already existing that embraces all physicians and veterans of all wars, the Association of Military Surgeons, to which many of us already belong, and, in the event that an organization is needed, that does fill the bill.

Consequently, I want to get this information before this gathering, so that you will have some of the background of the thinking that is going forward at the Wednesday meeting.

Dr Bagg stated that it was probably wise to follow Dr Conlin's point of view. During the year, as occasion arose, the President has tried to appoint veterans to the various committees in the Society, to take part in various functions of the Society, rather than as a separate branch. So long as Dr Conlin was speaking to the veterans, Dr Bagg suggested that he carry that as the point of view that the Society has been trying to follow.

The Secretary then spoke as follows

About two weeks ago Dr Kenneth A. Brown, of Weston (he is not a member of the Council), came into the headquarters of the Society and asked for information concerning veterans' affairs. I think Dr Brown is one of the moving spirits in this proposed veterans' organization. I spent an hour with him trying to explain to him that I was sure that the Massachusetts Medical Society, being made up of perhaps mostly veterans of some war, would see to it that veterans' affairs were considered as a very serious and important part of the Society's activities, and that if he would leave it to the men who are interested in the veterans' affairs in the Council and in the various committees and that if we could have a veterans' affairs committee, a new one perhaps appointed by the incoming president, his ends would be better met.

In the public interest to preserve, in the United States, our system of private medical practice

Familiarizing the public with the facts in connection with the values, the methods and the achievements of American Medicine.

To aid in the development of plans and to encourage the utilization of facilities that will result in the most widespread distribution of the most effective medical care and surgery

The Committee voted to approve the objectives of the National Physicians' Committee but disapproved some of the methods employed

Dr McKittrick moved acceptance of the report. The motion was seconded. Dr Bagg said that he had had a letter from Dr Allan M Butler, of the Committee, stating that he wished to change his vote and withdraw his approval.

Dr Bagnall said that Dr Butler's letter was not pertinent because surely the committee could not assume any responsibility for anything the National Physicians Committee did.

Dr McKittrick added that the subject of changing or attempting to change the policies of the National Physicians Committee had not been discussed.

Dr Bagg called for a vote, and the motion was passed. He assured Dr McKittrick that the subject was closed.

Dr Bagg then asked for final approval of the changes in the by-laws as printed and noted two errors in the use of "Inc" after Massachusetts Medical Service in the first paragraph.

Dr Bearse then pointed out that Chapter 4, Section 1, as amended, did not include the vice-president of the Society. Dr Bagg thanked Dr Bearse and called for a vote accepting the amended by-laws. The motion was carried.

*Committee on Physical Medicine* — Dr Arthur L Watkins, Middlesex South, *Chairman*

No new business had been referred to the Committee.

The Committee voted to approve the objectives of the National Physicians' Committee but disapproved some of the methods employed

Dr McKittrick moved acceptance of the report. The motion was seconded. Dr Bagg said that he had had a letter from Dr Allan M Butler, of the Committee, stating that he wished to change his vote and withdraw his approval.

Dr Bagnall said that Dr Butler's letter was not pertinent because surely the committee could not assume any responsibility for anything the National Physicians Committee did.

Dr McKittrick added that the subject of changing or attempting to change the policies of the National Physicians Committee had not been discussed.

Dr Bagg called for a vote, and the motion was passed. He assured Dr McKittrick that the subject was closed.

Dr Bagg then asked for final approval of the changes in the by-laws as printed and noted two errors in the use of "Inc" after Massachusetts Medical Service in the first paragraph.

Dr Bearer then pointed out that Chapter 4, Section 1, as amended, did not include the vice-president of the Society. Dr Bagg thanked Dr Bearer and called for a vote accepting the amended by-laws. The motion was carried.

*Committee on Physical Medicine*—Dr Arthur L Watkins, Middlesex South, *Chairman*

No new business had been referred to the Committee.

The American Board of Physical Medicine, Inc., had been approved by the Advisory Board for Medical Specialties and the first examinations had been conducted in Minneapolis in September, 1947, approximately 100 physicians had been certified to date.

An annual review of physical medicine was prepared for publication in the Medical Progress section of the *New England Journal of Medicine* entitled "Technical Advances in Physical Medicine."

*Committee to Make Recommendations for Directors of the Blue Shield*—Dr Leland S McKittrick, Suffolk, *Chairman*

The Committee submitted the names of the following men

To hold office until 1949

Mr. Eben H Ellison, Jr., Proctor Ellison Co., 26 South Street, Boston, to replace Mr Hugh Nawn

Mr Joseph K Milliken, Jr., reappointment.  
Dr Samuel A Robbins, reappointment.  
Dr James C McCann, reappointment.  
Mr Harold B Leland, reappointment.

To hold office until 1950

Mr Philip Morgan, reappointment.  
Dr Norman Welch, reappointment.  
Dr Arthur W Allen, reappointment.  
Mr J H Humphrey, reappointment.  
Mr Roswell Phelps, reappointment.

To hold office until 1951

Mr Benjamin Hull, Department of Labor and Industries, State House, Boston, to replace Mr Ernest Johnson.  
Mr Thomas G Brown, reappointment.  
Dr Elmer S Bagnall, reappointment.  
Mr Daniel J Boyle, reappointment.  
Dr Eugene Walker, reappointment.

Dr McKittrick moved the adoption of the report and it was seconded. Dr Bagg asked if there were any other nominations. There being none, the motion was put to vote and carried.

*Committee on Veterans Affairs*—Dr G Philip Grabfield, Norfolk, *Chairman*

The Committee on Veterans Affairs had held no meetings since its reappointment at the annual meeting in 1947. It was understood at that time that the Committee would not meet unless something arose that required its consideration or unless some individual or corporate body brought some subject to it for consideration. If no matters requiring consideration came up by the time of the Annual Meeting in 1948 it was the opinion of the committee that it should be discharged.

Dr Grabfield was not present, and Dr Bagg noted that the committee asked to be discharged. Dr Albert A Hornor, Suffolk, moved acceptance of the report. The motion was seconded.

Dr Lewis S Pilcher (Middlesex South) spoke as follows

Gentlemen, there is just one point I think should be brought out before we proceed to accept the discharge of the Committee. There is a group of younger veterans in the Society who have been quite dissatisfied with the Society's interest in veterans' affairs.

I am quite certain that if the Society discharges the Committee on Veterans Affairs, these veterans will form their own organization outside the Society, and take over the interest in veterans' affairs that previously had been the province of the Society.

This matter was discussed at the annual meeting in 1947. At that time representatives of the Society and of the Veterans' Committee very strongly opposed the formation of a Veterans' Medical Society outside the Massachusetts Medical Society, and promised the veterans who were present that the Society would adequately represent their interests and would take whatever action was necessary to rule out any complaints they might have, and to make adjustments that were necessary.

I do not know whether there is any need for such action or not, but obviously the Committee has taken no action and has taken no initiative. As the report states,

it was their understanding that nothing was to be done unless complaint was made.

I have no recommendation to make, one way or the other, except to mention the fact that if we discharge the Committee on Veterans Affairs, I know that the veterans will organize a society of their own outside the Massachusetts Medical Society.

They have already had their organizational meeting, and another meeting is, I believe, to be held tomorrow morning at the Copley Plaza Hotel.

I should be grateful if some of the men who are very familiar with veterans' affairs and medical circles would state what they feel, and whether we could accept the discharge of this committee, whether we should appoint a more active committee, or whether we should leave things to a veterans' society outside the Massachusetts Medical Society.

Dr Bagg replied as follows

Thank you for bringing up that matter. We were entirely ignorant of such a situation, because no reports had come to us at all, and there were no items to refer to Dr Grahfield's committee.

I will say this when I was getting together the list of committees last year, this committee seemed to be a very cumbersome one, and I have a feeling that a smaller committee, perhaps more actively made up of veterans themselves, might function better.

Therefore, the only way out of this situation that I can see is to refuse to discharge the committee, and then have a subsequent motion that the Committee be re-organized on the lines laid down.

Dr Bagnall then spoke as follows "It occurs to me that one way out of this would be to have this committee resign and let the president-elect, who will be the next president, appoint an appropriate committee, and that will take care of it all right."

Dr Bagg considered that a good suggestion. He stated that some definite information should be obtained from the veterans, adding that if the Society asked them for suggestions for appointments, that might solve the difficulty.

Dr John J. Curley, Worcester North, then spoke as follows

Last year the veterans met downstairs here, and we were promised that we would have either a section or some sort of committee within the Society that would be representative of the veteran physicians. This committee was appointed, and I know that one man in each district was appointed as a member of the committee, but to my knowledge, the man in my district was never asked to go to a meeting. So that whether the committee ever met or not, I do not know.

But the veterans, especially the veterans of World War II, who are physicians are especially desirous of having some section within the Massachusetts Medical Society. Whether it be a separate section or a separate society is up to the Society. But as we understood last year, the veterans were to have a committee and were to be allowed to form some sort of section within the Society, and to date nothing has been done about it.

Whether we need a new committee or whether we need some different type of committee or not, is the question.

But I can speak on behalf of the fellows who are councilors and who would make good live wires. I can think of a few men who could get this thing organized so there would not have to be any separate society within the state of Massachusetts.

A postcard notice has been sent out that there will be a meeting tomorrow. I should like to suggest to the President that he appoint somebody to go to that meeting

and speak for the Massachusetts Medical Society, as Dr Pilcher and I did last year at the meeting downstairs. And I think Dr Pilcher would be a very good one to send.

Dr John F. Conlin, Suffolk, spoke as follows

The matter of forming a new group is a matter that has been discussed quite a bit around the Commonwealth, and as long as it is this far on the agenda, I should like to rise to the point, although I am not a voting member of the Council. The chief argument that is put forth for organizing a veterans' group of World War II physicians is that they would be in a position to carry veterans' organizations along with them in the event that a matter such as compulsory national health insurance or something came up.

Whether that is enough to warrant a complete society or not, I hold in very serious doubt. I believe that just as much and just as effective work can be done by physicians working in existing veterans' organizations as members of those organizations, and spreading the word, whatever it may be.

Along that line, I believe very strongly, after covering the state, — and the things I saw here I hope to say at the meeting at 10 o'clock on Wednesday when the World War II physicians are in meeting, — that one of the greatest dangers in medicine right now is this tangle system of the successive groups that will grow up.

It has been said very well in recent days that first all the members of one specialty get together and form a society, then a college is formed within that society, and then an academy within that society, and then perhaps a board. And then there are multiple specialty groups. And in this monstrous growth we are losing sight of the district medical societies and the local groups that (and I do not think it needs any urging with this group) are the basis of our entire medical structure.

They come first and are the thing we are most interested in. The Society is based on district societies and the national organization is based on state societies. Consequently, unless a very definite need exists, we should not multiply societies.

There is an organization already existing that embraces all physicians and veterans of all wars, the Association of Military Surgeons, to which many of us already belong, and, in the event that an organization is needed, that does fill the bill.

Consequently, I want to get this information before this gathering, so that you will have some of the background of the thinking that is going forward at the Wednesday meeting.

Dr Bagg stated that it was probably wise to follow Dr Conlin's point of view. During the year, as occasion arose, the President has tried to appoint veterans to the various committees in the Society, to take part in various functions of the Society, rather than as a separate branch. So long as Dr Conlin was speaking to the veterans, Dr Bagg suggested that he carry that as the point of view that the Society has been trying to follow.

The Secretary then spoke as follows

About two weeks ago Dr Kenneth A. Brown, of Weston (he is not a member of the Council), came into the headquarters of the Society and asked for information concerning veterans' affairs. I think Dr Brown is one of the moving spirits in this proposed veterans' organization. I spent an hour with him trying to explain to him that I was sure that the Massachusetts Medical Society, being made up of perhaps mostly veterans of some war, would see to it that veterans' affairs were considered as a very serious and important part of the Society's activities, and that if he would leave it to the men who are interested in the veterans' affairs in the Council and in the various committees and that if we could have a veterans' affairs committee, a new one perhaps appointed by the incoming president, his ends would be better met.

than by any separate veterans' medical organization that tried to work perhaps at cross purposes with the Society

I thought he was convinced and I hope if somebody, from the Council appears at the veterans' meeting, that person will convince the whole group, because I think it is extremely important that no separate group appear medically, certainly, to work at cross purposes with this one

Dr Bagg stated that he would tell Dr Grabfield of the discussion and suggest that, inasmuch as he wanted to be relieved, he resign, and let the incoming president choose a new committee

*Auditing Committee* — Dr Howard B Jackson, Norfolk, Chairman, and Dr Frank T Downey, Middlesex South

The members of this committee were not present, and the President asked the Secretary to read the report. The Secretary read as follows

The Auditing Committee appointed the firm of Hartshorn and Walter, accountants and auditors, to audit the books and accounts of the Massachusetts Medical Society. This audit and account are hereby approved by us

The analysis of the revenues and expenses of the Society and the balance sheet of the condition of the funds of the Society have been inspected and approved by us

It was moved and seconded that the report be accepted. It was so voted by the Council

The President, according to the by-laws, stated that he would appoint two fellows, not members of the Council, as members of the Auditing Committee for 1948-1949. The President appointed the same fellows, Dr Howard B Jackson and Dr Frank T Downey

It was then moved that these appointments be confirmed. The motion was seconded and it was so voted by the Council

*Committee on Benevolence* — Dr Dwight O'Hara, Middlesex South, Chairman

The Committee on Benevolence had held one meeting, which Dr Ober attended by invitation, and had discussed the preliminary aspects of a plan to activate the desire of the Council to make provision for certain fellows or their families who have come upon hard times through no fault of their own. This was therefore a report of progress and merely indicated that the Committee hoped to submit definite recommendations at a future meeting of the Council

Dr O'Hara moved acceptance of the report. The motion was seconded and so voted

*Report of the Delegates to the American Medical Association*

The report was as follows

The first interim meeting of the House of Delegates of the American Medical Association was held in Cleveland, Ohio, on January 5 and 6, 1948. All your delegates or their alternates were present. Drs Phippen and Gear served on Reference Committees

The first business transacted was the selection of the recipient of the General Practitioners award. It was the first time the medal had been offered. There were 149 general practitioners suggested to the trustees by medical organizations, civic organizations, patients and others. Following the routine adopted for many years in awarding the Distinguished Service Medal, the trustees presented three names for the consideration of the House. After the ballot was taken it appeared that Dr Archer C. Sudan, of Colorado, had been chosen. Dr Sudan has practiced medicine in Kremmling, Colorado, a town of 567 population but with many outlying ranches. He has been interested in civic and public-health matters and has been president of the Colorado State Medical Society. He came on from Colorado and addressed the assembled general practitioners

The delegates to the World Medical Association were commended for their efforts in bringing about the formation of that organization last September in Paris. It was reported that forty-eight nations had joined together in the hope that such an organization would help to promote world peace as well as world health. The Permanent Secretary will have an office in the headquarters of the New York Academy of Medicine

The committee appointed last year to study the nursing situation brought in an interesting report of progress and believed they could offer a final report at the June meeting. Among other suggestions were bedside nursing under uniform standards and careful supervision, Social Security for nurses and the possibility of coverage of nursing service by insurance. Finally, a permanent committee was authorized to confer with the American Hospital Association and the American Nursing Association to study this problem

There was some discussion about limiting the tenure of office of members of the House, but it was finally determined that this matter should be left to each state society. As in any other business — costs have risen, and the American Medical Association faces a deficit of \$170,470 this year. Hence the House voted to raise the fellowship dues from \$8 to \$12

There was considerable discussion on the training and, more particularly, the distribution of interns. It was pointed out that many hospitals apparently are not living up to the gentleman's agreement to make their appointments on a certain specific day. Some believed that a year of rotating internship was advisable for any graduate in medicine — others thought the internship for general practitioners should be improved and lengthened. Finally, it was voted to set up a special committee on intern training and placement consisting of five members of whom two should be general practitioners — this committee to co-operate with the Council on Medical Education and Hospitals, and report at the next meeting

The perennial question regarding the practice of medicine by hospitals (that is, the employment of pathologists, radiologists and anesthetists directly by the hospitals, without staff status, and using the profits of their respective departments for general hospital purposes) produced several resolutions and much discussion. Many remedies and penalties were suggested, but it was finally left to a committee of five to confer with the various specialist organizations and to report at the next meeting. In the field of public relations several new workers were introduced but it was pointed out that each doctor in his daily contact with patients and their friends was the best possible agent for friendly relations with the public

These are some of the high lights of the session, which was conducted with dispatch and decorum

Dr Richard M Smith (Suffolk) moved that the report be accepted. The motion was seconded, and it was so voted

## NEW BUSINESS

Dr Leroy E Parkins, Suffolk, made a motion that the Committee on Postgraduate Assembly be

made a subcommittee of the Committee on Post-graduate Education

Dr Bagg, according to Council rules, referred the matter to the Executive Committee

Dr Bagg then read a letter from Dr John F Conlin urging the Society to conduct a health assembly in Massachusetts in 1949 Dr Bagg referred this matter to the Committee on Public Relations

Dr Augustus Thorndike, Suffolk, read the following resolution

Whereas at the October meeting of the Council the Committee on Rehabilitation and Industrial Health reported that a need existed for the establishment of a rehabilitation center in Boston under local management,

And Whereas the Secretary of State has issued a charter for the Bay State Medical Rehabilitation Clinic under local management,

Be it resolved that the President be authorized to appoint a committee of the Society to confer with the officers and directors of the newly formed Bay State Medical Rehabilitation Clinic and to consider in what manner the Society may best assist in the establishment of the clinic or clinics, the committee to report its recommendations with appropriate drafts of resolutions at the next meeting of the Council

Dr Bagg referred this matter to the Committee on Public Relations

Dr N S Scarcello, Worcester, presented the following statement

Disapproval is expressed of the manner of physician procurement and assignment as administered during the past war It is believed that any committee set up to determine the availability of fellow doctors for military service should be elected by the Society and not be an appointed body

Realizing that future warfare will be an all-out affair most likely involving a completely mobilized civilian as well as military population, a much more comprehensive plan for the utilization of physicians will be required than the relatively simple decision by a board regarding a doctor's dispensability or indispensability to the community

This matter, therefore, is one that involves not only doctors who were in military service during the last war (and who will be the first to be recalled in the event of another emergency) but also, most certainly, all doctors The problem thus requires the thought of the Society as a whole

It is therefore moved that the president of the Worcester District Medical Society be empowered to appoint a committee of seven to be known as the Committee of National Emergency Medical Service The duties of this committee will be to study the problem of physician mobilization in the event of national emergency, to keep the Society informed of state and national developments along these lines, and to make recommendations to the Society as occasion may arise

In view of the fact that the nation as a whole is preparing once again for national defense and that as a part of this plan the American Medical Association, under the supervision of the United States Government, is organizing a plan for obtaining physicians necessary for the needs of the armed forces, it is moved that the Worcester District Medical Society, through its councilors, place before the Massachusetts Medical Society a plan for procurement. Each district society within the Commonwealth will be instructed to elect a representative committee, to be known as "The National Emergency Medical Service Committee" One member of this committee shall be selected to represent his district on the State Executive Committee The State Executive Committee, which shall be composed of only the elected dele-

gate from each district, shall then elect a chairman, who will be designated as the Massachusetts representative head of the National Emergency Medical Service

Dr Bagg referred this matter to the Committee on Emergency Medical Service

Dr Robert W Buck, Middlesex South, read the following statement

The Massachusetts Physicians Art Association invites the Massachusetts Medical Society to sponsor officially an annual art exhibit to be held in connection with the annual meeting of the Society Our association is state wide in its membership and is made up of members of the Society In the past we have benefited greatly from the unofficial but generously given co-operation of the Executive Secretary and Committee on Arrangements Our purpose in asking official sponsorship is to simplify the problem of obtaining adequate show space farther in advance of the date of the annual meeting than our club has been able to do working independently and to ensure that the art show will be an annual affair

Dr Bagg referred this matter to the Executive Committee

Dr M J Schlesinger, Middlesex South, read the following resolution

Whereas the membership of the Massachusetts Medical Society includes a considerable group engaged solely in the practice of pathology and

Whereas this group has no specific identity other than general membership in the Society and

Whereas the problems peculiar to the practice of pathology make it desirable that this group be recognized as a well defined unit functioning within the structure of the Society and

Whereas the New England Pathological Society has been recorded as favoring the recognition of such a unit within state medical societies,

Be it resolved that the Council of the Massachusetts Medical Society is herewith petitioned to establish a Section on Pathology among the membership of the Society

Dr Bagg referred this matter to the Executive Committee

Dr Howard Root, Suffolk, then asked that the President be empowered to appoint a committee of not less than three and not more than seven to consider the possible action that the Society might take in the attempt to bring about better public understanding of diabetes, its early diagnosis and treatment

Dr Bagg referred this matter to the Committee on Public Relations

## COMMITTEE APPOINTMENTS

Dr Reardon read a list of nominations to committees for the year 1948-1949 Dr Reardon moved that the Council confirm his appointments The motion was seconded and carried

A motion to adjourn was made, seconded and carried The meeting adjourned at 11 05 p m

H QUIMBY GALLUPE, Secretary

## APPENDIX NO 2

## REPORT OF THE TREASURER

Increased membership in the Society and the return of more fellows to a civilian status has raised the income from resident dues from \$51,752 in 1946 to \$59,020 in 1947. Non-resident dues correspondingly increased from \$1776 to \$2244. *The New England Journal of Medicine* presented the Society with \$9000 in 1946 but was unable to contribute this year, \$5000 was advanced to the *Journal* in 1947, and paid back before the end of the year. In 1947, \$1335 was received from censor fees, as compared with \$1242 in 1946. Net profit from the Committee on Arrangements was \$6234, or \$966 more than last year. Profit from the New England Postgraduate Assembly was \$528, or \$193 less than last year.

The annual income from endowment funds rose from \$503 to \$548 and from the General Fund from \$5162 to \$5893, but fell in the Building Fund from \$1989 to \$1906. Profit from sale of securities was \$861 in the General Fund and \$1048 in the Building Fund. Subscriptions to *The New*

England Journal of Medicine from men in service fell from \$26 to \$76, which sum was turned over to the Journal office.

The book value of securities in the General Fund increased from \$179,094 to \$199,150 and in the Building Fund from \$9,665 to \$74,308. The endowment funds increased from \$23,166 to \$28,166 owing to the addition of \$5000 received by bequest from the estate of the late Samuel B Woodward, of Worcester, for the Cotting Fund.

Total revenue in the General Fund fell from \$78,072 in 1946 to \$76,679 in 1947, even in the face of increased income from dues, but this is understandable when it is recognized that the \$9000 from the Journal's activities is reflected in the 1946 figure. Total expenses rose from \$51,424 to \$64,630 in 1947, and increase in revenue over expenditure fell from \$26,026 to \$12,049. An income of \$76,679 on the basis of dues of \$10 confronted with a budget for expense of \$86,359 in 1948 explains why an increase in dues is unavoidable in 1948. It is practically certain that the budget for 1949 will be higher when provisions will undoubtedly be made or some sort of aid to members "who, through no fault of their own, find themselves incapacitated through illness, injury or age," and to "needy widows and orphans."

The total Building Fund assets stand at \$76,072 and total General Fund assets at \$243,226. The latter figure has not yet reached \$250,000, when by vote of the Council, any excess will be transferred to the Building Fund.

The Society ends 1947 with a grand total of assets in cash and securities of \$357,528, an increase of \$23,092 over 1946.

On advice of our investment counselors, the following changes have been made in the portfolio of investments. Conveyancers Realty debentures were sold, and the proceeds invested in American Telephone and Telegraph convertible 275 per cent bonds. Funds available throughout the year were invested in 10 shares of Hartford Fire Insurance Company, 25 shares of Chemical Bank and Trust, 25 shares of Cleveland Electric Illuminating Company and 100 shares of Southern California Edison 448 convertible preferred stock in the Building Fund. Corresponding investments in the General Fund included 25 shares of Hartford Fire Insurance Company, 50 shares of Fidelity-Phenix Fire Insurance Company, 10 shares of Guaranty Trust, 75 shares of Cleveland Electric Illuminating Company, 300 shares of Philadelphia Electric \$1 preference stock and 300 shares of Southern California Edison 448 convertible preferred stock. Certain long-term railway bonds and long-term Government bonds were sold to buy an equivalent amount of short-term Government bonds. This was advised because the firming of interest rates tends to depreciate the sales value of long-term bonds.

During the year a retirement plan policy was taken out for the one full-time employee who so far qualifies through length of service. The Postwar Loan Fund ceased making new loans at the end of the fiscal year, and the collateral held by the bank to cover these loans was reduced from \$25,000 to \$5000 inasmuch as seven loans made during the latter part of the year will run into 1948, \$1180 was paid to the Boston Medical Library, representing \$5 from each of the \$25 dues collected from 236 new members admitted in December, 1947. Although the Society is still exempt from income taxation, the Department of Internal Revenue has transferred the exemption from Section 101(6), corporations exclusively educational and charitable, to Section 101(7), corporations predominantly educational but making some profits. This change has brought with it our liability for federal old age and unemployment taxation, and state unemployment taxation, all coming under the Social Security regulations. An opinion was obtained from our legal advisers to the effect that the only thing was to concur in submitting to this taxation.

This year has been the first in which the Massachusetts Medical Society has had its exclusive office staff. The Treasurer wishes to express his appreciation of the very complex activities have been taken in hand, of the fine co-operation that has been shown and especially of the aid given by the Secretary handling his particular assignment.

### APPENDIX NO 3

#### REPORT OF THE EXECUTIVE COMMITTEE

President Bagge called the meeting to order at 4:00 p.m. The Secretary called the roll, members from Barnstable, Berkshire and Hampden were absent.

The report of the last meeting of the committee, held January 7, 1948, was accepted as printed in the April 7, 1948, number of the Journal.

#### COMMITTEE REPORTS

##### Committee on Public Relations

Dr. Bagge pointed out that Blue Cross and Blue Shield relations and problems seemed to be better and that the Blue Cross had to retain the special services in their contract to meet commercial competition and until a Blue Cross reserve fund is built up.

It was then moved, seconded and voted that the report of the subcommittee on Blue Cross and Blue Shield problems be approved. Dr. Bagge then stated that since the Executive Committee is the voting corporation of Blue Shield, the problems of Blue Cross and Blue Shield should be referred to this committee and that the subcommittee be discharged as approved by the Committee on Public Relations.

It was then moved by the Secretary that the subcommittee be discharged and that in the future Blue Cross and Blue Shield problems be handled by a subcommittee of the Executive Committee and that the President appoint such a subcommittee. The motion was seconded and passed.

President Bagge then mentioned the suggestion of a subcommittee (Chairman, Dr. Hagler) that each member of the Committee on Public Relations be asked to suggest to each district society that it set up machinery to handle calls for doctors at all times and that the Committee on Public Relations approve that method of action. The Secretary then pointed out that this subject was an extremely important one and that the Society office received many calls from people asking "Where can we get a doctor?" and

"Why don't doctors answer their telephones?" and "Why do doctors go away and leave nobody covering for them?" and "What happens on Wednesdays when every doctor is out of town?"

The Secretary said that he believed that this was a distinct duty of the Society, and that it had been so mentioned in the State Legislature and at the last meeting of the House of Delegates. He also said that the Massachusetts Medical Society is the only body able to take a step to see to it that the people get medical care when they need it. The Secretary moved that the action of the Committee on Public Relations on this matter be approved. The motion was seconded and passed unanimously.

It was then moved and seconded that the President appoint a committee to act in an advisory capacity in the procedure of transferring the Blood Bank from the Massachusetts Public Health Service to the Red Cross and in supervising the work thereafter. This motion was passed.

Dr. Bagg then stated that he had appointed Drs. Gallupe and John W. Spellman to work with the Hospital Presidents' Joint Committee to discuss voluntary hospital costs and to assist in passing Senate Bill 430, which was drawn to set up a purchasing commission to determine the costs of caring for patients whose bills are paid by a third party. The Secretary stated that he and Dr. Spellman had attended the meeting and had made it plain that they could not be held as representing the Society until the action of President Bagg had been approved by the Council. The Secretary then moved that the Committee approve the action of the President in appointing such a subcommittee and that the program instituted by the Hospital Presidents' Association be approved. The motion was seconded and so voted.

Dr. Root's suggestion that the responsibility of detecting untreated latent cases of diabetes should be borne by the medical profession was read by the Secretary. It was then moved and seconded that this matter be referred to the Committee on Public Health. It was so voted.

Dr. Bagg then complimented Dr. John Conlin for his work on the Nolen-Miles bill and commented upon the dinners given to the Legislative Committee on Public Health by the Committee on Legislation of the Society. Dr. Bagg also stated that the Committee on Public Relations had approved the employment by Dr. Conlin of an assistant (paid for out of his budget) to help him in his fight for this valuable legislation. It was then moved that the Committee recommend that this action be subject to approval by the Committee on Finance. The motion was seconded and so voted.

#### *Committee on Legislation*

It was moved that this informative report be accepted. The motion was seconded and so voted.

#### *Committee on Publications*

It was moved that this informational report be accepted. The motion was seconded and so voted.

#### *Committee on Ethics and Discipline*

It was moved and seconded that this informational report be accepted. The motion was seconded and so voted.

#### *Committee on Membership*

The Treasurer made two corrections and it was moved that the report be accepted. The motion was seconded and so voted.

#### *Committee on Public Health*

The Secretary moved that the Executive Committee endorse the program for the study of heart disease by the Massachusetts Department of Public Health in co-operation with the United States Public Health Service and Harvard Medical School. This motion was seconded and it was so voted.

#### *Committee on Medical Defense*

It was moved that the report of this committee be accepted. The motion was seconded and it was so voted.

#### *Committee on Society Headquarters*

It was moved that the report of this committee be accepted. The motion was seconded and it was so voted.

#### *Report of the Treasurer*

It was moved that this report be accepted. The motion was seconded and it was so voted.

The Treasurer remarked that up to April 2 he had received \$113,414 in dues and \$2298 in nonresident dues. The Boston Medical Library had been paid \$22,380. Men had paid their dues by the first of March than had last year. Dr. Phippen said that the Library Trustees were very grateful and that they had started to do what they could to put the Library on a firm, working basis. He stated that the Library was being talked about all over the Commonwealth and that it is a place worth talking about.

#### *Committee on Expert Testimony*

This report recommended that the Committee be a standing committee and that it co-operate with the Committee on Ethics and Discipline and the Committee on Medical Defense. The committee would act as a clearing house for all cases in which ordinary or expert medicolegal testimony is concerned.

It was moved that the recommendations of the committee and the proposed amendment to the by-laws be approved. The motion was seconded. In the discussion it was brought out that by-law changes should be referred to a committee for that purpose. It was also brought out that so-called "listeners" would be used in cases concerning malpractice suits and that these "listeners" could be requested by counsel on either side and that there would be no fees paid to "listeners." The President called for a vote on the above motion, and it was so voted.

#### *Committee to Meet with the Massachusetts Hospital Association*

It was moved that the report be accepted. It was seconded and so voted.

#### *Committee on Postgraduate Medical Education*

It was moved that the report be accepted and the recommendations in it be approved. Dr. Bagg pointed out that the committee wants suggestions regarding its activities and is open minded about having clinics rather than didactic lectures. The motion was seconded and so voted.

#### *Committee on Medical Economics*

It was moved by the Secretary to accept the report and approve the committee's approval of the objectives of the National Physicians' Committee, but to disapprove of some of the methods employed by that organization. This motion was seconded, and it was so voted.

#### *Committee on Physical Medicine*

It was moved that the report be accepted. The motion was seconded and so voted.

#### *Committee to Make Recommendations for Directors of Blue Shield*

It was moved to accept the report. The motion was seconded and so voted.

#### *Committee on Veterans' Affairs*

The Secretary moved that this committee be discharged. The motion was seconded, and it was so voted.

#### *Committee on Benevolence*

The President remarked that when the Society dues were increased benevolence was to be considered and that he was authorized to appoint a Committee on Benevolence. Dr. O'Hara was good enough to act as chairman and the others accepting were Drs. Badger, Buck, Hubbard and Lund. It was moved to accept the report. The motion was seconded and so voted.

#### *Report of the Delegates to the House of Delegates of the American Medical Association*

It was moved to accept the report. The motion was seconded, and it was so voted.

#### *OTHER BUSINESS*

Dr. Bagg suggested that it would be in order to make a motion to have appointed a standing committee to consider and properly to write suggested changes in the by-laws and that the Committee on Council Rules might be expanded for this purpose. It was then moved that it be recommended to the Council that the Committee on Council

ules he made a standing committee on constitution and by-laws and council rules. This motion was seconded and was so voted.

The Secretary gave each member a copy of the changes in the by-laws already approved by the Council and written properly by Dr Hornor at the request of the President. The President stated that he would take it for granted that they were approved by the Executive Committee unless errors had been detected. No errors were noted.

Dr Bagg then stated that the Council had previously recommended a committee on emergency medical service and that he had received an acceptance from Dr Reginald Fitz, as chairman of such a committee.

Every state governor has been asked to set up a program to care for emergencies and the Massachusetts Medical Society committee would be expected to co-operate with the Governor's committee. It was moved that the recommendation of the American Medical Association to activate such a committee be approved. The motion was seconded and so voted.

The Secretary then stated that he had attended a meeting of the Council on National Emergency Medical Service at Chicago, April 5 and 6, at the request of Dr Bagg. The purpose of the meeting was to acquaint the doctors with the civilian-defense problems of an atomic war and to present a resolution against a special draft call for physicians.

Dr Bagg then presented a request from the Biological Laboratory Department asking for support from the Society in getting more money to maintain and continue their work in Rh blood testing. It was moved that the Executive Committee go on record as favoring the expenditure of public funds for the maintenance of this service. The motion was seconded and so voted.

A motion to adjourn was made, seconded and so voted.

H QUIMBY GALLUPE, *Secretary pro tempore*

## APPENDIX NO 4

### REPORT OF COMMITTEE ON PUBLIC RELATIONS

The meeting of the Committee was held at the Harvard Club at 6 00 p m on March 3, 1948. In addition to the representatives of thirteen district societies there were present President Edward P Bagg, who acted as chairman of the Committee, Dr Daniel B Reardon, president-elect, Dr H Quimby Gallupe, secretary of the Massachusetts Medical Society, and Dr John F Conlin, Director of Medical Education and Information.

The report of the Secretary, as printed in the advance notice of the meeting of the Council on February 4, 1948, was accepted.

A resolution was adopted that in the future the meetings of the Public Relations Committee be held at 5 00 p m on Wednesday, but not on the second Wednesday of the month.

Dr Charles D McCann, chairman of the Committee on Blue Cross-Blue Shield Problems, presented the following report.

A meeting of the Sub-committee of the Public Relations Committee was held at the Harvard Club, Boston, on January 28, 1948, with the following members of the Society present: Edward P Bagg, president, H Quimby Gallupe, secretary, Nicholas Scarcello (Worcester), Charles G Hayden, medical director of the Blue Shield, Albert A Hornor (Suffolk), Harold R Kurth (Essex North), and Charles D McCann (Plymouth).

The resolution of Dr Scarcello, "That the Blue Shield, through its employees, determine accurately an applicant's yearly earnings before issuing a policy and secondly, that these earnings be reviewed each year," was discussed and it was learned that a new system of notification was being tried out in Worcester District, and that if this new form proved satisfactory it would be extended into all the districts of the Society.

Dr Scarcello was satisfied with this progress.

The resolution of the Middlesex North District Medical Society, that the Blue Shield fees be increased, was discussed, and Dr Hayden reported that the Blue Shield lost about \$12,000 last year, but that if the fee table was right in 1939 the payments to physicians should be increased.

The situation, brought to light by Dr S A Dibbins, Middlesex North, whereby bills of patients hospitalized for diagnosis were paid in some cases and not in others, was discussed, and the Committee had the assurance of Dr Hayden that the condition would be corrected.

A report by Dr Scarcello, Worcester District, on the lack of information given members of the Society regarding Blue Cross and Blue Shield, was discussed, and Dr Hayden stated that the presidents of the district societies had been asked to appoint an administrative committee to work with the Blue Cross and Blue Shield, and through this committee better information would be available to the members of the Society.

The resolution of Dr Bernard Appel, Essex South, that "The medical staff of the Salem Hospital unanimously opposed the inclusion of professional services in the Blue Cross policy," was discussed, and the Committee voted to bring this resolution before the Public Relations Committee.

The meeting was adjourned at 10 15 p m.

ALBERT A HORNOR

HAROLD R KURTH

CHARLES D MCCANN, *Chairman*  
of the Sub-committee of the  
Public Relations Committee

This report was accepted by the Committee on Public Relations. A motion was then proposed and adopted that this committee be discharged, and that any future problems with reference to Blue Cross and Blue Shield be directly referred to the Executive Committee of the Council, which is the corporate body of the Blue Shield.

President Bagg reported to the Committee on Public Relations that at a Directors' Meeting of the Blue Cross he presented the report of the Special Services Committee. This report was approved by the Directors in principle, but it was felt that at present the special services of roentgenology, pathology, and anesthesiology must continue as part of the Blue Cross coverage to meet the competition of the regular insurance companies. It was felt that as the financial condition of the Blue Cross improved, more consideration could be given to the recommendations of the Special Services Report.

Dr Frederic Hagler, Hampden District, reported for his subcommittee. At present all calls and inquiries with reference to physicians that were being sent in to headquarters were being dispersed to the respective district secretaries. It was felt that this procedure was very unsatisfactory and at times quite confusing. As a result of this report Dr Nicholas S Scarcello, Worcester District, presented the following resolution.

That each member of the Public Relations Committee present to his District Society the problem of handling such calls and inquiries and that each District Society set up the machinery whereby such calls and inquiries could be satisfactorily handled.

When such an organization has been created the district secretary will so inform the secretary of the Massachusetts Medical Society of the procedure. This resolution was adopted.

President Bagg reported that there had been numerous complaints and criticisms that it was becoming increasingly difficult to obtain medical service during the night, on holidays, and over week ends. Dr James V McHugh offered the following resolution as a solution of this problem.

That the question of medical coverage for nights, holidays, and week ends be presented by each member of the Public Relations Committee to his district medical society, and that the district medical society initiate such programs as will satisfactorily solve this situation.

This resolution was also adopted.

President Bagg requested that the Committee on Public Relations recommend that he, as president of the Massachusetts Medical Society, be empowered to appoint a committee that would act in an advisory capacity in the procedure of transferring the Blood Bank from the Public Health Service to the Red Cross. This recommendation received unanimous support.

Mr Arthur G Rotch, a member of the Hospital Presidents' Association, had recommended the setting up of a council for the study of the cost of voluntary hospitals. He had requested President Bagge to appoint two representatives of the Massachusetts Medical Society to this council. The Public Relations Committee endorsed this request.

A booklet entitled "Our Bay State 'Dreyfus' Scandal and Snake Pits," by Lockwood Myrick, a member of the Massachusetts Legislature, has been sent to each member of the Public Relations Committee. It was the unanimous expression of the members that the secretary of the Public Relations Committee write Mr Myrick an appreciative letter of his report with reference to the state of mental hospitals in Massachusetts. The following letter was sent to Mr Lockwood Myrick by the Secretary.

As Secretary of the Public Relations Committee of the Massachusetts Medical Society I have been directed by that Committee to send you this letter of appreciation of the booklet which you have sent to each member of our Committee.

It is the opinion of the Committee that you have given much time, thought, and effort to this report concerning the state of mental hospitals in Massachusetts. One finds much information here which will serve as a basis for serious thought and consideration on the part of the medical profession.

Dr Howard F Root, Suffolk District, called to the attention of the Committee that according to a survey made by the United States Public Health Service there are probably close to a million undiscovered or latent cases of diabetes in this country. The American Diabetes Association, composed of a thousand physicians interested in diabetes, has appointed a committee to consider means of discovering these latent cases. This committee is considering a "Diabetes Week" for some time in November or December. It was Dr Root's opinion that it would be a great advantage if a concerted effort to carry out this program was made by proper publicity and local committees under the supervision of the medical profession. He furthermore felt that it was the responsibility of the medical profession to seek out these untreated latent cases of diabetes rather than to have lay organizations or public health officials initiate such a program. The Public Relations Committee endorsed Dr Root's opinion.

Dr John F Conlin, Director of Medical Education and Information, stated that he had complete confidence in the eventual passage of the Nolen-Miles Pound Bill.

He stated that it would soon be necessary for him to have an assistant to help him prepare some of the special material that is necessary in the proper function of his office as Director of Medical Education and Information. This part-time public relations assistant would require a supplementary budget of approximately \$1500 a year. The Committee recorded itself as endorsing this recommendation.

The meeting adjourned at 9 30 p m

HAROLD R KURTH, Secretary

## APPENDIX NO 5

### COMMITTEE ON LEGISLATION

Since January 1, 1948, the Committee on Legislation has reviewed and taken action on seventy-nine bills coming before the State Legislature this year. In general it opposed any legislation that, in its opinion, would lower the standards of medical care in the Commonwealth, or would transfer the responsibility for the treatment of the patient from a local to a state level. The Committee observed that, whereas it could approve of a number of bills in principle, many were so loosely drawn as to permit unpredictable expansion and possible participation of the state in the field of personal health services for individuals.

The Sub-Committee on National Legislation continued to study bills coming within the scope of its special interest. It approved the objectives of the National Science Foundation Act of 1948 (HR4852), preferring, however, that the director of the Foundation be approved by the President, by and with the consent of the Senate from a panel of nominees selected by the members of the Foundation.

Attention was called to S 2189, a bill to "assist the State in the development and maintenance of local public health units and for other purposes," drawn up by the Association of State and Territorial Health Officers. This bill has been commended to the president of the Society by the Massachusetts Commissioner of Public Health. Whereas the American Medical Association has recorded its approval of federal aid to assist in the development of local health units under point two of the Ten-Point National Health Program, the Board of Trustees have placed emphasis on the principle that medical care and treatment are not properly functions of public-health units. The Committee, in reviewing S 2189, approved of the broad principles of the bill, but believed that it should contain restrictions that would make it clear that the Surgeon-General may not, by regulation, require that local health units engage in treating the sick. Section five (B) (4) permits the surgeon-general of the Public Health Service, by regulation, to prescribe the "types of health services" that shall be considered basic health services.

On March 3, 1948, Senator Saltonstall called hearings on S 1290. This bill calls for the development of school health services defined as being "services for the prevention, diagnosis, and TREATMENT of physical and mental defects, and conditions of school children." The bill calls for no means test, and would use public funds for services to those unable to pay their own way. The Committee on Legislation was not given sufficient notice to consider this bill, and it is mentioned in this report only to call it to the attention of the Society.

GEORGE R DUNLOP, Chairman

## APPENDIX NO 6

### COMMITTEE ON PUBLICATIONS

*The New England Journal of Medicine* and the Massachusetts Medical Society sustained a great loss in the death of Dr Robert N Nye, on September 10, 1947. Dr Nye had been editor of the *Journal* since January 1, 1937, so that his tenure of office was nearly eleven years. When the Massachusetts Medical Society purchased the *Journal*, Dr Walter P Bowers became the editor. He managed it so well that, when he relinquished his responsibilities to Dr Nye, it had already become recognized as a journal of outstanding merit. Dr Nye built upon the solid foundation that Dr Bowers had established, and, at the time of his death, the *Journal* was one of the best medical weeklies in the country. Dr Nye brought to the duties of editor a keen mind, an acute business sense, a critical, scientific judgment and a commanding personality. He was devoted to the best interests of the *Journal* and the Massachusetts Medical Society. His superior abilities are evidenced by the progress the *Journal* made under his editorship.

On January 1, 1937, the total circulation of the *Journal* was 6131, and only 1006 copies went to others than members of the Massachusetts Medical Society. At the end of 1947, 25,001 copies of the *Journal* were distributed—19,241 to others than members of the Society. This is a clear demonstration of the fact that the *Journal* is now a national medical publication and that its high quality is appreciated beyond the confines of the Society. In 1936, the last year before Dr Nye became editor, the income from advertising was \$19,984.65, in 1947, income from this source was \$117,804.23. The total operating expense for 1936 was \$58,682.56, and for 1947, \$240,630.54. In 1937, the Society contributed \$20,500 toward the publication of the *Journal*—a cost of approximately \$4.00 per member. For the past three years the *Journal* has been published without expense to the Society, and the *Journal* has paid to the treasury of the Society the sum of \$31,800. This is a record of which the *Journal* and the Society may well be proud. The Committee on Publications pays affectionate and admiring tribute to Dr Nye.

The Committee was confronted with a grave responsibility in appointing a new editor of the *Journal*. It was fortunate, in the interim, that Miss Davies' devotion and mastery of all the details of publication, and Mr O'Leary's editorial skill, made possible the uninterrupted publication of the *Journal*. We appreciate, also, the loyalty and unselfish service of the office staff during this period. Dr Nye, when he was taken ill, had asked Dr Garland to be acting

ditor during his absence, and he continued in that capacity, it the Committee's request. Dr Garland performed this interim service at a real personal sacrifice, and the Committee is appreciative of this. The Committee, after due consideration, appointed Dr Joseph Garland as editor, and he assumed his duties on November 1, 1947. Dr Garland has been associated with the *Journal* for many years as a member of its editorial board and as an editorial writer. The Committee is grateful to Dr Garland that he was willing to accept the editorship. It involved the relinquishment of his private practice and a complete readjustment of his activities. The Committee is confident that the *Journal* will continue to go forward under his guidance and congratulates itself and the Society upon its good fortune.

During the year 1947 *The New England Journal of Medicine* continued to expand. As of the issue of December 25, *Journals* were sent to 14,375 regular subscribers, — a gain of 2301

upon prior to January 1, 1947, became effective. These changes should result in a moderate increase of income, which will help to offset the increased costs of publication.

During the year the Editorial Board has considered a total of 306 manuscripts, of which 188, or 64 per cent, were accepted. The corresponding figures in 1946 were 292 and 201, and, in 1945, 203 and 129. The number of text pages increased from 1834, in 1946, to 2000 in 1947.

New, machine-coated paper stock has become available and will be put into use as soon as the old stock is exhausted. This will make a great improvement in the appearance of the *Journal*, particularly in the reproduction of cuts.

The outlook for 1948 appears good, although no one can predict with certainty what economic conditions may prevail. An abundance of manuscripts seems assured, which permits the Editorial Board to exercise even higher standards of acceptance than formerly.

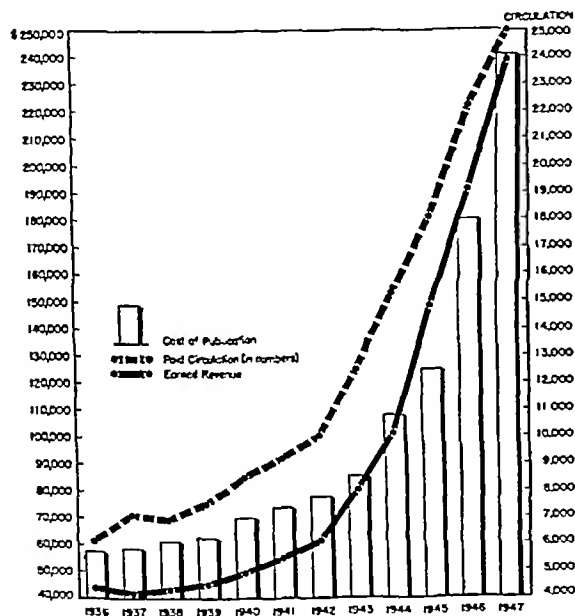

On January 1, 1948, a pension plan for employees of the *Journal*, which had been considered for a long time, came into operation for three individuals. Other members of the staff will be added to the plan as they become eligible. The expenses of the *Journal* will be increased about \$3500 yearly. This amount will be modified later by dividends and additional pensions.

The Registry of Fellows was published in 1947 and distributed to Members of the Council and to the Officers of District Medical Societies. The cost was \$1,515.31.

A summary of the financial transactions for the year is appended to this report. The accounts have been audited by Hartshorn and Walter. Their report and the detailed financial report are in the hands of the Treasurer of the Society.

OLIVER COPE  
JOHN FALLON  
JAMES P. O'HARE  
CONRAD WESSELHOEF  
RICHARD M. SMITH, *Chairman*

## NEW ENGLAND JOURNAL OF MEDICINE

over 1946, 4081 student subscribers, — a gain of 779 over 1946, 5770 members of the Massachusetts Medical Society, — a gain of 390, 251 "once-a-month" subscribers from the New Hampshire Medical Society, 219 "regular" subscribers from the New Hampshire Medical Society, 172 exchanges, 58 complimentary recipients and 75 advertisers, — a total circulation of 25,001, as compared with 21,384 at the end of 1946.

The publication cost of the *Journal*, including all charges for printing, binding, mailing and stock, was \$165,062.16 in 1947, as compared with \$120,531.42 for 1946. The total costs were \$240,630.54, as compared with \$180,327.86 for 1946. The revenue from advertising was \$117,804.23 in 1947, as compared with \$93,345.21 in 1946. The revenue from subscriptions in 1947 was \$106,916.22 as compared with \$84,792.33 in 1946. The total revenue for the year was \$224,720.45 as against \$188,140.52 for 1946. There was a net loss of \$1081.61 in 1947 as compared with a net profit of \$11,277.71 in 1946. A new item of expense was added in 1947, amounting to \$3684.78 for policies under the new Employee's Pension Plan.

The \$5000 appropriated by the Society for the *Journal's* use, which had been expended in the purchase of paper, was returned to the Treasurer at the end of the year.

On January 1, 1948, subscription rates were increased to \$7.00 per annum for regular subscribers, and \$4.00 for New Hampshire regular subscribers and for students. Also, on that date, the increased advertising rates determined

## APPENDIX NO 7

### COMMITTEE ON ETHICS AND DISCIPLINE

The work of the Committee during the past year has been varied and interesting. The usual number of complaints by laymen against physicians are of the usual type, overcharging, improper treatment and refusal to attend emergencies. These have been considered and resulted in clearance of the doctors involved. A third of the complaints were based on the refusal of doctors to attend an emergency. Following the report of the findings of the Committee to the plaintiffs several letters were received, each one closing with the comment "another vote for socialized medicine."

Seventeen requests for advice regarding ethical procedure have been received. These varied from questions concerning newspaper insertions of notices announcing opening of

office for practice to questions about the doctor's duty to his patient while on the witness stand. Two inquiries recently received asked, "Was it ethical for an expert witness to charge ten per cent of the total sum received as damages in a tort case as his fee for giving testimony in the plaintiff's behalf?" and "Was it ethical for a doctor, having referred a patient to a surgeon who sent his bill and was paid, and the doctor having sent his bill and been paid, to ask the patient for an additional amount equal to fifty per cent of the surgeon's bill for referring the case?" Most of these inquiries were answered by the Chairman, the answers being referred to the Committee for approval and in many instances a letter was received from the inquiring doctor thanking us for our advice.

While these complaints and inquiries constituted a greater part of the work of the committee, there have been numerous complaints of more serious nature. These resulted in conversations with the chairman and hearings before the full Committee and were decided by the Committee.

A group of cases were of such importance that they should be mentioned here briefly.

First, a complaint was received against a fellow for deliberate violation of Section 4 of Chapter 3 of the Principles of Medical Ethics of the American Medical Association. Investigation showed that the fellow was guilty as charged. This is considered a more serious infringement as the fellow had been advised previously by the Committee regarding his procedure in these matters. He was severely reprimanded by the Committee and was told that his future connections with the Society would depend upon his subsequent actions in this regard. The case was placed on file.

Second, two complaints against fellows of sex perversion were received. The first fellow was convicted in a Court of lewd practices. After thorough investigation, the Committee decided that the defendant was more sinned against than sinning. He was cautioned by the Committee and the case placed on probation, pending any further complaint. The second complaint against a physician was of improper actions during the course of an examination. The doctor denied the truth of any such accusations. Owing to the lack of corroborative evidence on either side, no action was taken. This case was also placed on file.

Third, a complaint was received from a certain welfare society in a neighboring city charging two doctors with having entered into a conspiracy to aid and abet the adoption of an unborn child under "black market" methods. The director of the society appeared and claimed that this practice had been going on for some time in her city and was viewed by her society with a good deal of concern. After consultation with an attorney she brought it to our attention. A hearing was given to her and to the parent of the child. The doctors in question were called in consultation with the chairman and by him referred to the full Committee. Following the hearings of the two doctors before the Committee, it was their unanimous opinion that the doctors had been unethical and were guilty as charged. They were so informed. The penalty for this act was taken under advisement. Following this meeting, subsequent investigation brought forth evidence that one of the doctors, attempting to intimidate the plaintiff, brought threats against her that would definitely violate Section 1 of Chapter 2 of the Principles of Medical Ethics. The other doctor was found to be definitely guilty of attempts at extortion. A second discussion was carried out at the December meeting of the Committee, and the decision of the Committee again postponed to the January meeting. At the meeting on January 24, the matter was again discussed, and it was unanimously voted by the Committee that the two erring fellows be asked to resign from the Society. A request to this effect was sent to each of them and their resignations followed. These resignations were sent through the usual channels to the Committee on Membership for action, and the case was considered closed.

In closing we wish to call attention once again to the number of complaints received from disgruntled laymen concerning the attitude of the members in responding to emergency calls. This is not restricted to members of the

Massachusetts Medical Society. It seems to be prevalent throughout certain parts of New England. It is the duty of all of us to see that no action on the part of any of us should detract from the honor and dignity and usefulness of the Society.

RALPH R. STRATTON, *Chairman*

## APPENDIX NO 8

### COMMITTEE ON PUBLIC HEALTH

As secretary of the Public Health Committee of the Massachusetts Medical Society, I herewith submit the resolution of that Committee that "we endorse in principle and support" the following Heart Disease Epidemiological Studies to be conducted by the Massachusetts Department of Health, Harvard Medical School, and the United States Public Health Service. Dr. Vlado Gettung, Commissioner of Public Health, has requested such endorsement. These studies have the approval of the New England Heart Association. The Executive Council of the New England Heart Association constitutes the Advisory Committee to the conducting the program.

The first of the two studies referred to above is known as "The Heart Disease Epidemiology Study." This will consist of examination and long-term follow-up study of a sample adult population in the city of Framingham to detect what will be considered an average incidence of heart disease. Arrangements have been completed with the Framingham Union Hospital, the physicians in the community and the local board of health for co-operation. Findings in individual cases will be communicated to the family physician. The duration of the study will be approximately five years.

The second aspect of the study is known as "The Public Health Aspect of Heart Disease." Its objective is to find ways further to reduce cardiovascular disease and conserve cardiac function in the general population. The Board of Health of Newton has invited the Department of Public Health to use the City of Newton for this purpose. It is planned to develop the Public Health Nursing aspect, morbidity and mortality reporting and health education. It is also planned to promote the general study of heart disease and control methods in the community by such agencies as the Newton Medical Club, Newton-Wellesley Hospital, Newton Health Department, Visiting Nurses Association, Social Welfare Groups and so forth. The proposed duration of this study, which will be limited to heart disease among adults, is three years. It is recommended that the Council, at its next meeting, approve endorsement of the above by the Society.

JOHN J. POUTAS, *Secretary*

## APPENDIX NO 9

### COMMITTEE ON INDUSTRIAL HEALTH

This report is informational only for the reason that the chief efforts of the Committee during the year were devoted to the convention or annual meeting of several professional groups held in Boston in the latter part of March and early April. It seemed impractical to prepare the Committee's report on or before March 15, 1948, the deadline for publication in the circular of Advance Information for the Council. It seemed desirable to delay the report to evaluate the work of the Committee.

In September, 1947, the Committee was asked by and agreed with the officers and directors of the American Association of Industrial Physicians and Surgeons and affiliated groups to function as the Local Arrangements Committee and to prepare the program for the annual meeting of the Association, to be held in Boston from March 27 to April 4, 1948, inclusive, and to co-operate with the several committees representing the Conference of Governmental Hygienists, American Association of Industrial Hygienists, American Association of Industrial Dentists and American Association of Industrial Nurses.

The scientific meeting of the Association of Industrial Physicians and Surgeons began with a clinical conference at the Massachusetts General Hospital on Tuesday morning,

March 30, continuing on that afternoon at the Boston City Hospital and thereafter at the Hotel Statler on the following three days

Many members of the Massachusetts Medical Society graciously gave their time and talent to participate in the program, and their presentations were very well received

There was a total registration of 1652 persons. In attendance were physicians and nurses engaged in or interested in industrial health from nearly every state in the Union, many from Canada and a few from foreign countries

It has been stated verbally over and over again and reported by uncounted letters that the meeting was an outstanding success

The Committee expresses its appreciation and its gratitude to the members of the Society who helped to make this

national meeting on industrial health the success that it has been acclaimed

Two of the members of the Committee with the Chairman represented the Society at the Congress on Industrial Health of the American Medical Association at Cleveland in January. That also was a successful meeting, as one would expect it to be under the management of Dr. Carl M. Peterson, secretary of the Council of Industrial Health of the American Medical Association

Other activities of the Committee were confined to offering suggestions and help to a few industrialists interested in organizing medical services in their plants, meeting with industrial nurses concerning their particular problems and directing physicians interested in industrial work toward potential positions

DANIEL L. LYNCH, *Chairman*

## CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

### Weekly Clinicopathological Exercises

FOUNDED BY RICHARD C. CABOT

BENJAMIN CASTLEMAN, M.D., *Associate Editor*

EDITH E. PARRIS, *Assistant Editor*

#### CASE 34301

##### PRESENTATION OF CASE

*First admission.* A fifty-eight-year-old woman was admitted to the hospital complaining of pruritus and jaundice

She was perfectly well until five months before admission, when she first noted persistent generalized pruritus. Two months later the stools became lighter, and the urine became "tea colored." Two and a half months before admission the pruritus became intense, and icterus of the skin and scleras appeared. Her appetite became poor after the onset of jaundice, but in about two weeks it returned to normal. There was no abdominal pain, back pains, chills or fever. Except for an occasional sensation of epigastric pressure following meals, she had had no gastrointestinal symptoms until the onset of the present illness.

There was no history of alcoholic intake, ascites, intolerance to fatty foods or previous jaundice and no history of drug habits or blood or plasma transfusions. One month before the onset of pruritus she visited relatives, two of whom were in bed with jaundice (allegedly, "infectious hepatitis").

Physical examination showed the skin and scleras to be icteric. There was slight palmar erythema, which was prominent at the fingertips. About the cheeks, neck, arms, trunk and legs were numerous "pea-to-bean-sized, soft, intracutaneous cysts." Numerous café-au-lait spots were present over the trunk bilaterally. No spider angiomas were present.

The liver edge was palpable three fingerbreadths below the costal margin and was smooth and nontender. The spleen could not be felt.

The temperature was 98.6°F, the pulse 80, and the respirations 20. The blood pressure was 125 systolic, 80 diastolic.

Examination of the blood revealed a white-cell count of 7700, with a normal differential. The hemoglobin was 12 gm.

The urine was normal, no bile was present. Urinary urobilinogen varied from 0.4 to 1.8 Ehrlich units. The stools were brown, formed and guaiac negative. The prothrombin time, which was 55 seconds, promptly returned to normal after one dose of vitamin K. The van den Bergh reaction was 2+ mg per 100 cc direct, 2.7 mg indirect. The cephalin-flocculation test was + in twenty-four and forty-eight hours. The serum albumin was 4.12 gm, and the globulin 2.56 gm per 100 cc. The alkaline phosphatase was 12.5 units. A week later the van den Bergh reaction was 1.3 mg per 100 cc direct, 1.8 mg indirect. The cephalin-flocculation test was negative, and the alkaline phosphatase was 22.9 units per 100 cc. A bromsulphalein test demonstrated 35 per cent retention of the dye in forty-five minutes.

X-ray examination of the chest and a gastrointestinal series were negative. There was no evidence of widening of the duodenal loop. The gall bladder did not concentrate the Graham dye, and no opaque stones were seen.

During the three weeks of hospitalization the patient was entirely afebrile and felt exceptionally well except for mild pruritus. Jaundice gradually subsided clinically and by chemical tests.

*Second admission* (two months later). At home the patient was on a high-vitamin, high-calorie, high-carbohydrate diet, with pyribenzamine for the pruritus. For about six weeks she felt well, except for pruritus, which was most severe at night. She gained 6 pounds. However, after this interval slight jaundice reappeared, the urine became dark, and she was readmitted to the hospital.

On examination the scleras were muddy and the skin deep tan. She complained of severe pruritus. Physical signs were unchanged since the first ad-

mission The prothrombin time was normal, the thymol turbidity 10 unit per 100 cc, thymol flocculation negative, cephalin flocculation negative in twenty-four hours and ++ in forty-eight hours The van den Bergh reaction was 2.6 mg per 100 cc direct, 3.7 mg indirect A bromsulfalein test demonstrated 41 per cent retention of the dye

On the fifth hospital day an operation was performed

DIFFERENTIAL DIAGNOSIS

DR EARLE M. CHAPMAN There was no history of blood or plasma transfusions We can exclude homologous serum jaundice by that statement

We do not know whether the relatives who were sick in bed with "infectious hepatitis" had Weil's

hepatitis, biliary cirrhosis and an obstructive process due to a silent stone in the common duct, to stenosis of the duct or to tumor

We are presented with a wealth of laboratory data, and yet this evidence does not point clearly to which one of the above horses is going to win the race I think it is fair to say that no one can make a positive diagnosis in such cases of jaundice by means of laboratory technics We are still searching for a reliable test that will differentiate the mildly or intermittently obstructive type of jaundice from the jaundice caused by intrinsic liver cell damage In this case the clinician first made a diagnosis of hepatitis and so allowed the patient to go home Then, when she became more jaundiced with bile in the urine and yet gained weight,

TABLE 1 Laboratory Findings in Favor of Portal Cirrhosis or Hepatitis and Biliary Cirrhosis, with or without Obstruction

DISEASE FAVORED	ALKALINE PHOSPHATASE	VAN DEN BERGH REACTION		BROMSULFAL- EIN RETENTION	CEPHALIN FLOCCULATION	OTHER DATA
	units/100 cc	DIRECT mg/100 cc	INDIRECT mg/100 cc	%		
Portal cirrhosis or hepatitis	12.5	2.4	2.7	35 and 41	++ in 48 hr	Dark stools
Biliary cirrhosis with or without obstruction	22.9	2.4	2.7	35 and 41	—	Low urobilinogen prompt response to vitamin K

disease, infection due to *Leptospira canicola* or other infectious hepatitis

One wonders if the "intracutaneous cysts" were spread out and also in the liver That is a rarity I would not put past the Pathology Service to spring on me

May we see the x-ray films?

DR STANLEY M. WYMAN This is a single postero-anterior film of the chest and shows no gross evidence of disease in the lung fields or in the heart The diaphragm is not remarkable The film of the stomach and duodenum shows a grossly normal-appearing stomach The duodenal cap is better seen on several spot films and is probably not remarkable There is a strong suggestion on several spot films of a pressure defect on the medial aspect of the wall of the second portion of the duodenum at about its midpoint

DR CHAPMAN I would like to interrupt at this point to say that such an observation is not recorded in the protocol

DR WYMAN I may be wrong, but I think there is a small pressure defect on the wall, present in almost all the films The Graham test shows no evidence of excretion of contrast substance, and I see no opaque stones There is some dye in the stomach, which might explain why the gall bladder did not excrete the dye

DR CHAPMAN The differential diagnosis here appears to be one of the most difficult ones in clinical medicine — namely, between infectious

he decided that there might be biliary obstruction Surgical procedures are then the only way to make a positive diagnosis by obtaining a liver biopsy or exploring the whole biliary tree, or both This may occasionally surprise all hands by effecting a brilliant result by removal of a silent stone in the common duct or alleviating the chief symptom of itch by T-tube drainage in cases of so-called xanthomatous biliary cirrhosis

Unfortunately, the Graham test is of little aid in such a case The liver cell is injured, and so the iodine dye cannot get through into the biliary passage in sufficient amounts to render the gall bladder opaque, and we have learned that about 20 per cent of gallstones do not cast a shadow

Let us make a scoreboard of the laboratory tests and see which side is favored (Table 1) All the tests indicate damaged liver cells, and the low total protein indicates that the duration of damage was long enough to interfere with the blood protein manufacture But what we would like to know is whether the injury is from back-pressure or intrinsic disease

The first consideration is the urobilinogen test. Damage to the liver cells causes them to lose the ability to convert urobilin and urobilinogen into bile pigment, with the result that these bodies accumulate in the blood and are excreted in the urine This change precedes the appearance of actual bile pigment by a considerable time. Watson<sup>1,2</sup> applied this color reaction to this same

differential diagnostic group and found that in jaundice due to stone there was no increase in the urinary urobilinogen *except* in the presence of a complication such as acute cholecystitis, cholangitis, obstructive cirrhosis or severe anemia. However, in hepatitis a marked increase in urinary urobilinogen was usually found. In this case the low value favors obstructive jaundice.

Now a word about the alkaline phosphatase reaction. Roberts,<sup>3</sup> an Englishman, was the first (in 1933) to note an increase in plasma alkaline phosphatase in some cases of obstructive jaundice. A study of the level of this enzyme was originally put forward as a means of distinguishing obstructive from nonobstructive jaundice. It tends to be higher in biliary cirrhosis or obstructive jaundice than in hepatitis. Here we have a slightly elevated value at first favoring hepatitis and later a higher figure in favor of obstruction.

We have all been disappointed by the failure of the van den Bergh reaction to point a diagnosis for us. In obstructive jaundice the pigment in the plasma is mainly of the direct-reacting type, accompanied by an appreciable amount of the indirect-reacting type. In hepatitis, and in hepatitis with cirrhosis, both kinds of bilirubin are found in proportions resembling that obtained in obstructive jaundice. A positive direct van den Bergh reaction may not differentiate obstructive from nonobstructive jaundice. It must be kept in mind that all serums giving a direct reaction also give a positive indirect reaction, but the reverse does not always hold true. Thus, I have put the van den Bergh test in both columns in Table 1.

The cephalin-flocculation test was at first negative and later slightly positive, so that this test is inconclusive, as is the bromsulfalein test. The dark stools obviously favor a nonobstructive process, whereas the prompt response to vitamin K is frequently seen in obstructive jaundice.

Thus, the laboratory evidence finishes in a dead heat. The poor doctor has to fall back on his hunch, his horse sense or his clinical experience. And as I look over this situation, I am going to call it biliary cirrhosis. If the patient had had xanthelasma or high cholesterol value I would favor the rare nonobstructive form. As it is, I hope that a common-duct stone was discovered. And why do I say this? Because of two points — she maintained a good appetite and gained weight despite a jaundice that waxed and waned.

I shall never forget a patient under the care of experts, who pointed out that all the tests indicated clearly that the poor man had a hopeless cancer of the head of the pancreas, and there was nothing to do for him. When Dr. Arlie V. Bock visited and from a distance of thirty feet saw the man devouring a huge meal, he simply said, "No man with cancer would eat like that. We will explore him

for stone." The patient had a huge gallstone wedged in the common duct.

DR. EDWARD L. YOUNG: What is the advantage of a liver biopsy?

DR. DANIEL ELLIS: In this case a liver biopsy was not done because there was a feeling that the patient had either nonobstructive biliary cirrhosis or obstructive jaundice and that we would consequently not have been able to differentiate the cause in the biopsy specimen. If the diagnosis of infectious hepatitis had been entertained, it would have been worth while to do a biopsy.

I would like to take issue, in a friendly way, with Dr. Chapman. I realize that he was listing the laboratory findings and discussing the figures from an academic standpoint. I do not believe however that we can let the laboratory findings go without saying that here is a case in which obstruction played some part, as indicated by the laboratory findings. I do not believe that there is anything in the reports given that would really allow us to make a diagnosis of infectious hepatitis, and Dr. Chapman arrived at the same conclusion. The important thing about the alkaline phosphatase is the increase in titer between the two determinations. An alkaline phosphatase of 12.5 units is considered high in this laboratory. Usually with hepatitis one finds it below 10 units. The fact that at one time it was 12 and the next time 22 units is in favor of obstructive jaundice or so-called biliary cirrhosis. The van den Bergh reaction cannot be counted on, as Dr. Chapman has pointed out. In the presence of jaundice the bromsulfalein test does not tell much. The cephalin-flocculation test mentioned in the discussion is essentially normal. So that all in all, one should not have arrived at a diagnosis of infectious hepatitis.

As to why this patient was allowed to go home, I find myself in the position of not having the old record here so I do not know what I wrote at that time. So far as I recall, Dr. Fairlie and I saw the patient on the ward at the request of the Service, and we thought that she had obstructive jaundice of some kind and that there was a possibility that she had so-called biliary cirrhosis. We thought that we would lose nothing by sending her home and following her closely in the Out Patient Department for a limited period. We set the maximum limit of time for her to stay away at four weeks. At the time of discharge the jaundice had disappeared, and there seemed to be so much improvement clinically that we let her go. We saw her four weeks later, at that time the improvement had continued. The itching was a very minor problem four weeks after discharge.

DR. CHAPMAN: Do you attribute that to the pyribenzamine?

DR. ELLIS: I do not know. It does help some patients.

DR C W FAIRLIE The patient felt that pyribenzamine definitely helped her although she did not continue it.

DR ELLIS At the end of four weeks we felt justified in continuing the observation. When she came in three weeks later there was no question that she had jaundice again, and the itching had returned. Dr Fairlie saw her and thought that she should be admitted for exploration.

DR CHAPMAN The whole complexion of this was changed by the surprise finding brought out in the x-ray film. In the light of that finding one has to listen to the X-ray Department very closely. This obstruction is demonstrated very nicely on this film, even though the laboratory evidence is not conclusive. The only thing that could produce this is cancer of the head of the pancreas.

DR WYMAN I have seen a stone wedged in the ampulla produce a similar picture.

DR BENJAMIN CASTLEMAN If this was a tumor how do you account for the intermittent jaundice?

DR ELLIS It is a common belief that cancer does not lead to intermittent jaundice. That is not true. Time and time again in the presence of common-duct stone the jaundice waxes and wanes and one should not be misled by the fact that the patient's symptomatology is relieved for a short time only to recur.

#### CLINICAL DIAGNOSIS

Obstructive jaundice

#### DR CHAPMAN'S DIAGNOSES

Common-duct stone

Cancer of the head of the pancreas (after additional x-ray interpretation)

#### ANATOMICAL DIAGNOSIS

*Adenocarcinoma of duodenum at ampulla of Vater*

#### PATHOLOGICAL DISCUSSION

DR CASTLEMAN Intermittent jaundice is very often a clue in locating the site of the tumor because it is well known that tumors at the ampulla of Vater become necrotic and a great deal of the necrotic material sloughs out, relieving obstruction for a time. That is what was found in this case—a tumor of the duodenum beginning at the upper edge of the ampulla of Vater and extending for 3 cm into the pancreas, obstructing, of course, the common bile duct. The tumor was a well differentiated adenocarcinoma, but it had invaded the entire wall of the duodenum. A Whipple operation was performed, and the patient is still on the ward. How is she at present, Dr Fairlie?

DR FAIRLIE She is well.

DR CASTLEMAN There were no metastases to the regional lymph nodes.

DR CHAPMAN Did you do a biopsy of the liver?

DR CASTLEMAN The liver looked all right to the surgeons. The common bile duct, removed with the specimen, was markedly dilated, measuring 3 cm in circumference in some places, further evidence that it was a fairly slowly growing tumor.

DR CHAPMAN Then the X-ray Department actually made the diagnosis.

DR ELLIS They did not make the diagnosis when they had the chance. Dr Wyman just made it this morning.

#### CASE 34302

#### PRESENTATION OF CASE

A twenty-one-month-old girl entered the hospital because of respiratory distress and cyanosis. Pregnancy had been uneventful, and delivery normal. The first year of the child's life was unusual only in that the birth weight was not regained until two months of age and that during the first winter she suffered numerous colds. These were characterized by three to four days of coryza and dry cough. The weight at one year of age was 18 pounds, and development appeared to be entirely normal. At about this time, however, the child ceased gaining weight, and the stools became foul smelling, although they were not described as ever being bulky, fatty or foamy. Four months after admission the appetite, which had previously been excellent, began to fail, and the child lost her bright, alert personality. Vomiting, abdominal pain, constipation, diarrhea and melena were all denied. Rectal prolapse occurred on two occasions. Respiratory difficulty, consisting of a chronic, dry cough, also appeared approximately one year before admission, and four months before admission a chest x-ray film was said to have shown chronic bronchitis. For this sulfadiazine was given—two tablets each day until the time of admission. Two or three weeks before admission the cough became productive of whitish phlegm, dyspnea on exertion developed, and grunting noises in both phases of respiration were noted. During the three days before admission respiratory difficulty increased, and the child became cyanotic on one occasion. Physical examination showed a poorly nourished, pale, apprehensive girl. The throat contained a thick, whitish, mucoid secretion. The intercostal spaces retracted on inspiration, as did the lower border of the rib cage. Expiration was grunting. The chest was hyper-resonant to percussion. Fine

dry rales were heard throughout on inspiration, and squeaks and rhonchi throughout on expiration. The heart was unusual only in that the left border of cardiac dullness could not be percussed. The liver edge was felt three fingerbreadths below the costal margin.

The temperature was 101°F, the pulse 150, and the respirations 60.

The hemoglobin was 12.2 gm, and the white-cell count 13,800, with 51 per cent neutrophils. The urine showed an occasional white cell. A stool was described as brown, soft, greasy and foul smelling. Tuberculin and blood Hinton tests were negative. Cultures of the nose and throat grew abundant colonies of *Staphylococcus aureus*. An x-ray film of the chest showed widespread infiltrative changes in all lobes with areas of consolidation and atelectasis interspersed. Both leaves of the diaphragm were low. A vitamin A tolerance test gave the following figures: fasting levels in the serum, 0.2 unit of vitamin A per cubic centimeter (normal 0.4 to 1.0 unit), and 0.2 unit of carotenoids per cubic centimeter (normal 1.0 to 3.0 units), after oleum percomorphum (0.1 cc per kilogram of body weight) 0.7 unit of vitamin A per cubic centimeter and 0.3 unit of carotenoids per cubic centimeter. A duodenal drainage was not done.

The patient was given penicillin, sulfadiazine, oxygen and intravenous fluid. The temperature rose daily to 100 to 101°F, the pulse varied from 110 to 188, and the respiratory rate from 30 to 60. Respiratory difficulty increased. Terminally, circulatory collapse appeared. A transfusion was given, but the beneficial effect was only temporary, and the patient died on the fifteenth hospital day.

#### DIFFERENTIAL DIAGNOSIS

DR NATHAN B. TALBOT: I should like to take a chance and guess at the outset that this patient had pancreatic fibrosis. That condition is well described in an article by Blackfan and May,<sup>1</sup> published in 1938 and in another article by May and Lowe<sup>2</sup> reported in 1948. If my guess is wrong, at least these are good references to have at hand.

The symptoms and signs to be reviewed may be divided into three groups: gastrointestinal complaints, respiratory symptoms and metabolic changes.

Regarding the gastrointestinal signs it is noteworthy that this child failed to regain her birth

weight on time and even after the neonatal period gained only at an abnormally slow rate. In addition, there was during the neonatal period a diarrhea, with green stools. Somewhat later the stools were described as putrid. Such stools are suggestive of steatorrhea. Though we do not have objective measurements of stool-fat content, we have measurements of the vitamin A and carotenoid concentration values in the serum. Both of these were abnormally low. Moreover the vitamin A level failed to rise normally following a standard dose of material containing vitamin A. Since vitamin A and carotene are lipid-soluble materials, failure of normal absorption of these substances suggests failure of fat absorption and hence is consistent with the thought that there was steatorrhea. Steatorrhea such as this child presumably had can be caused by a variety of conditions as well as by pancreatic fibrosis. Thus, the diagnosis of pancreatic fibrosis must rest upon more than this evidence alone. A positive diagnosis of pancreatic fibrosis could have been made by analysis of fluid obtained by duodenal drainage for pancreatic enzyme activity. Pancreatic fibrosis is about the only condition in which alkaline duodenal fluids are found to be entirely devoid of pancreatic enzyme activity.

Regarding this child's respiratory symptoms, it will be remembered that there had been a dry cough since birth. As time went on the respiratory signs took on the characteristics of mixed, partial and complete bronchiolar obstruction—namely, rapid respiration, scattered fine rales, low diaphragm and x-ray findings suggestive of emphysema and possibly scattered atelectasis. Perhaps we should look at the x-ray films. I expect to see scattered patches of atelectasis and possibly actual pneumonitis, with a low diaphragm on both sides indicative of generalized emphysema.

DR JOSEPH HANELIN: There is a tremendous amount of pulmonary emphysema. There are marked bulging of the thorax anteriorly and posteriorly and a low, flattened diaphragm, with scattered areas of density throughout the lung field, fairly typical of the picture that Dr Talbot has been describing.

DR TALBOT: Because of the expiratory grunt I should not be surprised if there was some evidence of pleuritis. I think I see some thickening of the pleural line along the periphery.

DR HANELIN I cannot see it

DR TALBOT In conjunction with these pulmonary findings we are told that there was a predominant growth of *Staph aureus* in the sputum. For some reason this is very characteristic of patients of this sort. They almost always have *Staph aureus* in the sputum, and they are apt to have a *Staph aureus* infection of low grade in the pulmonary tract.

We may now consider the third group of signs, which are predominantly of metabolic nature. The serum carbon dioxide content was increased, and the serum chloride concentration was slightly decreased. Although we do not have a measurement of the serum pH, I would be willing to say that the high carbon dioxide value was due to a failure of excretion of carbon dioxide by the lungs with a compensatory decrease in serum chloride and acidosis due to the retained carbon dioxide. This illustrates the fact that an elevation of the carbon dioxide does not necessarily mean alkalosis. It can signify a respiratory acidosis. While we do not have measurements of the oxygen content of the blood we were told that the patient suffered from cyanosis. Presumably this was due to a failure of absorption of oxygen just as we have evidence that there was a failure of excretion of carbon dioxide because of the pulmonary pathologic process.

Before closing our comments we may be permitted to make a guess about the pathological findings. I expect inspissation of the secretions of certain excretory passages, especially the pancreatic acinar ducts, the bronchiolar-gland ducts and also possibly the salivary-gland ducts. Proximal to the obstruction caused by this inspissated material there should be dilatation of the passages and of the acini. In addition, there should be an apparent, if not a true, fibrosis of the surrounding tissues. In the lungs one may also find low-grade scattered pneumonitis, possibly bronchiectasis and possibly even small pulmonary abscesses. In addition, there may be signs of vitamin A deficiency with metaplasia of epithelial elements. Fatty infiltration of the liver would not be surprising.

The differential diagnosis is, I think, rather limited. Tuberculosis can be ruled out on the basis of a negative tuberculin test. Monilia infection might conceivably cause the picture, but there is nothing specifically indicative of that disease. Patients born with congenital malformations of

the gastrointestinal tract (malrotation of the large bowel and so forth) may suffer from chronic nutritional disturbances, but they are not apt to have pulmonary changes. Chronic infection located almost anywhere in the body may also cause chronic gastrointestinal insufficiency. Celiac disease and celiac syndrome are terms often applied to such nutritional disturbances when they are not due to pancreatic fibrosis. The possibility of a pancreatic cyst with nutritional disturbance should be mentioned. However, patients with these conditions ordinarily do not have the combination of pulmonary and nutritional signs indicated here. The only exception to such a statement that might be considered is chronic pulmonary disease resulting in a secondary, functional type of chronic intestinal insufficiency. For these reasons I will make the diagnosis of fibrosis of the pancreas my first and only choice.

DR PERRY CULVER I want to emphasize that Dr Talbot used the presence of pulmonary changes to make the diagnosis of pancreatic fibrosis as contrasted with the other form of celiac syndrome.

DR MARTIN QUINN In general, what is the prognosis?

DR TALBOT Prior to chemotherapy the majority of patients died at about the age that this child died. However, occasional children with this disease live much longer. Antibiotics such as penicillin and streptomycin given by injection or by aerosol inhalation, or both, may prolong life expectancy to an appreciable extent by retarding the development of pulmonary changes. Unfortunately such chemotherapy does not cure the disease, it merely acts to ameliorate it temporarily.

#### CLINICAL DIAGNOSES

Emphysema  
Pneumonia (diffuse), *Staph aureus*  
Pancreatic fibrosis

#### DR TALBOT'S DIAGNOSIS

Pancreatic fibrosis

#### ANATOMICAL DIAGNOSES

*Pancreatic fibrosis*  
Acute and chronic tracheobronchitis, *Staph aureus*  
Pulmonary emphysema  
Fatty infiltration of liver

## PATHOLOGICAL DISCUSSION

DR TRACY B MALLORY Autopsy showed extensive fibrosis of the pancreas with inspissated secretions in the small ducts and dilatation of the acini as Dr Talbot prophesied. We did not demonstrate similar changes in any other organs and, unfortunately, the salivary glands were not examined. We might have seen them there. The bronchial tree was filled from top to bottom with a purulent exudate. There was considerable peribronchitis and some actual increase in fibrous tissue around the bronchi. The alveolar tissue was emphysematous, and there were almost no foci of atelectasis or pneumonia. The process stopped abruptly at the terminal bronchioles. The one other organ that showed well marked changes was the liver, which weighed 450 gm. It was the only organ in the body that had not shrunk considerably below normal weight. This enlargement was obviously due to very extensive stores of fat.

DR CHARLES LOWE Dr Talbot asked me to say a few words about the manner of death in children with this disease. It is interesting that most people assume that fibrosis of the pancreas is a nutritional problem, and therapy is directed accordingly. However, I think that most youngsters who die with this disease do so from one of three causes, none of them nutritional. The first cause is an overwhelming infection. Some of this group show extensive pneumonia, abscesses and empyema. The second group undoubtedly die as much from anoxemia as anything else. Their elevated carbon dioxide reflects it. The third group die from right-sided heart failure with anasarca. They are the least understood. As you already know, the present patient showed relatively little pulmonary fibrosis at autopsy, while the electrocardiogram showed right-axis deviation. For this we have no explanation.

DR MALLORY I think it might be quite similar to the situation in chronic bronchial asthma, in which a significant number of patients eventually die of right-sided heart failure, even though the degree of anatomic emphysema is not very great. I think that permanent overdilatation of the lung probably causes resistance to the flow of blood in

the pulmonary arteries just as prolonged atelectasis does. I believe that alternation of expansion and contraction of the alveoli is necessary to normal circulation of blood through the lungs.

DR JAMES HEYL Might I ask about the bronchial and salivary-gland secretion? I cannot see the connection with pancreatic fibrosis.

DR MALLORY I cannot answer that. Dr Lowe, can you?

DR LOWE All one can say is that at autopsy one occasionally finds some disease of the parotid gland and the salivary ducts. Rarely, one sees some dilatation of the secreting glands in the bronchi. I am sure it is the extraordinary case and not the ordinary one that shows these changes, however.

DR MALLORY There may have been occlusion of the glands in the bronchial wall in this case. We were not able to demonstrate any changes of vitamin A deficiency. Presumably the child died too rapidly for that.

DR CULVER Would you care to say anything about your concept of the etiology of pancreatic fibrosis?

DR MALLORY I do not believe I have the right to. I know too little about it.

DR JAMES H TOWNSEND Would anyone care to? How about you, Dr Talbot?

DR TALBOT No, but I should like to ask Dr Mallory if he accepts the thesis that it is inspissation of the secretion of these glands that causes the trouble.

DR MALLORY We occasionally see in adults fairly marked inspissation of secretion in the pancreatic ducts, which does not result in cystic disease or fibrosis. It presumably appears and spontaneously disappears again, but I am not sure that we really know that. It can be rather marked and for some reason that I do not understand, I saw a great deal in soldiers during the war but I have seen very little in civilian life.

## "OF THEE I SING"

THE communication from Dr. A. J. A. Campbell published elsewhere in this issue of the *Journal* calls attention to a situation that requires prompt and decisive action. The Veterans Administration, apparently unaware of the consequences of such a policy, seems to have drawn a blank check designed to pay for the medical education of any presumably qualified United States veteran in any medical school of Europe.

The warning is sounded by Dr. J. L. Lochner, Jr., to whose paper in the *Journal of the American Medical Association* Dr. Campbell refers.\* Dr. Lochner briefly reviews the recent history of European medical education as it has affected

\*Lochner, J. L., Jr. Licensure evaluation of European medical graduates. *J. A. M. A.* 137:16, 1948.

practice in this country. For a half century prior to 1913 European standards of education were high, but they suffered a serious and prolonged eclipse after the first world war. An invasion of the United States by graduates of foreign schools began about 1926. In the face of this sharp increase in the number of immigrant physicians seeking admission to practice, many states stiffened their requirements for licensure.

In New York State particularly, for which Dr. Lochner speaks, the record established by foreign physicians taking examinations in the last two decades has not been good, the over-all failures have amounted to 66 per cent, with over 72 per cent failing in the period from June, 1945, to February, 1947.

The present policy of the New York Board of Regents has resulted. Graduates of European medical schools who matriculated since January 1, 1940, are not admitted to the New York State medical licensing examination, with the possible exception of those whose medical courses were completed in the Universities of Cambridge or of London, the University of Dublin or the University of Ireland. The laws of Massachusetts, in similar manner, currently permit the registration of no graduate of any foreign school of medicine, Canada excepted, who matriculated later than January 1, 1941.

In the face of the qualifying restrictions that have been established by the various states of the Union, some admittedly more lax, some more stringent than others, the Veterans Administration now offers to those citizens for whom it has accepted a considerable degree of responsibility a free ticket to attend medical school in postwar Europe at Government expense! The list of schools approved, so far as can be ascertained, is all-inclusive. Santa Claus does not intend to miss a chimney or leave a stocking empty.

The effect of such a policy on the standards of medical practice in this country can be imagined; we may hope that we will not need to witness it. Those states now maintaining high standards will refuse to admit to practice the newly returned doctors with their ersatz sheepskins — until the pressure builds up. Then the standards will go down. In a free country such as this no legislature can continue long to deny the right to practice to those veterans

who have been educated at the taxpayers' expense — nor, in a free country, can those responsible for the demolition of the standards be required to employ these same poorly trained physicians for the care of their own families

It is not only in respect to medical education that this indiscriminate largess is being distributed. Under the title "Veterans' Training The \$500,000,000 Boondoggle," *Collier's* published in May an analysis of the situation. *The Reader's Digest* presented the *Collier's* story in condensed form the following month.

The Veterans Administration, according to this report, is presently engaged in spending a half billion dollars on a veterans' school program that includes, in addition to foreign-made medical education, courses in flying, ballroom dancing, bartending, amateur photography, piccolo playing, radio and television engineering and chicken sexing. The last named classic, consisting in the identification of the sex of newly hatched chicks, may be mastered through a four-week \$40 course in Missouri or a seven-month \$500 course, with subsistence, in Illinois. It all depends.

And so the great University of America operates, all paid for out of Uncle Sam's pants pockets, with courses ranging from piccolo playing to amateur photography, from chicken sexing to a complete curriculum in foreign schools of medicine, now mainly low grade no matter how famous they might once have been or how excellent they may again become.

Of these various activities, the encouragement of those to whom a debt of gratitude may be owed, to become ill trained physicians, represents the most serious mistake. All the good will in the world toward the country's veterans should not be allowed to promote this particular folly, rather should a true regard for their welfare cause its abandonment forthwith.

---

#### PHILOSOPHIA MEDICI

"'For this' he said, 'is the great error of our day in the treatment of the human body, that physicians separate the soul from the body.'"

After nearly twenty-five hundred years, this comment from Plato<sup>1</sup> is still an apt criticism of the medical profession. Now the advocates of psychosomatic medicine, proclaiming the truth again, deserve well of their patients and of their fellow-practitioners for their effort to correct this "great error of our day." Whether they will be able to provide a more adequate and enduring corrective than that offered by Socrates the Great Gadfly can be determined perhaps only after the lapse of another two and a half millennia.

A modern sage, Alfred North Whitehead,<sup>2</sup> says that philosophy asks the simple question "What is it all about?" He defines speculative philosophy as the endeavor to construct a system of general ideas "in terms of which every element in our experience can be interpreted."<sup>3</sup> It is the comprehensiveness of the philosophical scope that needs emphasis.

In the narrower view of the practicing physician, speculative philosophy is often too recondite for him to be at home in it, and perhaps for many physicians the upper limit of attainment will be an awareness that their special field has implications in and connections with the vast body of knowledge that represents the intellectual side of civilization.

The beginning student of medicine, sometimes clearly called, sometimes vaguely but no less strongly drawn, to this way of life, asks the question "What is medicine all about?" The reply by contemporary medical education is not satisfying. It shows him great accomplishments of science in the past, active progress in the present and promise of greater things to come. But what answer does he receive, if he goes on to say, "I want a philosophy of medicine?" Perhaps a cynical smile and a shrug of the shoulders and the words, "It is enough for you to be a scientist, science is to be your life." If he is offered more, it is likely to be a materialistic philosophy.

The student will fashion his own philosophy in time, but what the medical school should do is assist him, as it does all too little today, in acquiring a sense of direction and in becoming familiar with and at home in the great humanistic tradition in which some of the finest flowers of the profession have had their roots. In this tradition there are

many names, but three come to mind at once Sir Thomas Browne, Sir William Osler and Harvey Cushing. Of the first it has been said, "A certain air of mystery and consecration, as of one dedicated, for whom nothing could be common or unclean, to whom his own life seemed 'a common miracle of thirty years,' and the visible world 'a hieroglyphical and shadowed lesson' of the thoughts of God, surrounded the man from childhood to old age."<sup>1</sup> The dedication of Osler is clear in his writings and was constantly manifest to those who were associated with him. Cushing<sup>2</sup> wrote of the "Consecratio Medici" as one having immediate knowledge

"There were giants in the earth in those days." Their culture was broader and their roots deeper, and part of their secret we know: they contemplated greatness. With gifts beyond the ordinary, they transmuted and transmitted it with the stamp of their own personality set upon it.

Today, as one looks around, how many physicians are there to be found who have so grasped the principles of the science and of the art of medicine that it can be said of them that they know what it is all about? Fortunate is the medical school that has on its faculty even one such wise man. His influence may be supplemented, but not replaced, by the study of the lives of other wise physicians of the past, and such study may be a stimulus and an inspiration to the young physicians, even in the absence of a notable example on the faculty.

The great need in medical education today is not to direct less attention to the science of medicine and to its training and development of specialists but to make a new and vigorous effort to foster in the student a wise philosophy of the science and of the art, in the hope that there may result therefrom the fairest of all gifts that the physician can possess, an understanding heart.

#### ON THE PRIZING OF LIFE APART FROM ITS CONTENT

SHOULD the medical interest in old age and the dollars spent in pharmaceutical research on its diseases be matched by the hoped-for effective prevention, the second age of dependency may equal the hitherto allotted life span, and could be twice as long as man's productive life. The Pharmaceutical Medical Research Foundation plans to spend a quarter of a million dollars on degenerative disease. Dr. Edward L. Bortz, president of the American Medical Association, on the basis of animal physical maturity and life expectancy, thinks that man should live to be a hundred and fifty years old. Unless physical well-being and, even more important, unless productive activity is provided for the aged, not the first but the last hundred years will be the hardest and will be a dog's life indeed.

There is no doubt that the population is aging, that men over fifty are less readily employed in industry than formerly and especially so if partially disabled by degenerative disease. The medical care, the rehabilitation and the productive employment of the aging and the aged is already a serious medical and social problem. How often we see a widow alone in her room, with no one to mother or mend for, depressed that she is no longer needed, her children long since busy with their own young families. How often we see the once competent man, now retired, depressed and becoming decayed in person, irritable and contentious in minor affairs or, sadder of all the prey of chance delusions — professional, political or amorous. To live on indefinitely and idly with old-age assistance may be more cruel than to be allowed an earlier and peaceful terminal illness.

Geriatrics is not a medical specialty but is a field of human endeavor with medical and sociologic aspects and with many potential resources of manpower. In its medical aspect geriatrics, like pediatrics, refers to general medicine applied to a particular age group. Cosin\* has made some pertinent suggestions for organizing a geriatric department in the hospital system providing for acute geriatric wards for investigation and treatment, long-stay

\*Cosin, L. Organizing geriatric department. *Brit. M. J.* 2:1044-1046, 1947.

annex wards for patients permanently bedfast, long-stay annex wards for frail ambulant patients and the resident-home type of accommodations for the more robust patients. He discusses the requirements of the medical-staff nurse, orderly and practical nurse according to need. In a large community of this country, such as Boston, an organization of this sort might be worked out. A close relation could be established between privately endowed homes for the aged and general hospitals, some of the income of the former being allocated for beds in the latter. The homes for the aged could care for long-stay patients in two divisions, one for the bedfast and one for the frail ambulatory. The general hospital might provide visiting physicians and specialists of various sorts, including experts in rehabilitation, nurses, dietitians and externs. The advantages would be mutual. Finally there should be home care of the aged living in families or in boarding houses on old-age assistance with social-service supervision from the hospital or state social service.

Undoubtedly, the most important emphasis should be on rehabilitation and re-employment graded from occupational therapy for the bedfast through "made work" for the frail ambulatory and simple piecework brought to the home, to light domestic service, outside tasks, timekeeping and baby sitting for the aged on old-age assistance. "The length of days is vanity," said the preacher, and it has been said again by the philosopher who decried our "uncritical prizing of life apart from its content." In our plans to spend brains and money on lengthening our days let us allocate a goodly portion to devising ways of filling them with suitable and rewarding labor.

### MILIARY LESIONS OF THE LUNG

MANY diseases that have come into prominence in recent years have been associated with miliary infiltrations of the lung. The more recent of these include such diverse conditions as the viral pneumonias, certain bacterial pneumonias, pulmonary lesions in Q fever and other rickettsial diseases, histoplasmosis, beryllium and cadmium poisoning, bagassosis, Loeffler's eosinophilia and acute diffuse

interstitial fibrosis of the lung — to mention only a few. Some of the better known conditions, such as sarcoidosis and miliary tuberculosis, have now assumed new significance from a differential diagnostic point of view because of the effectiveness of streptomycin in acute miliary tuberculosis.

Many of these miliary diseases of the lung are of considerable interest and offer puzzling problems to the internist. In 1942 Austrian and Brown<sup>1</sup> were able to list twenty-two separate states in which miliary lesions of the lung were encountered. Their list was based on personal clinical observations made over almost a quarter of a century and supplemented by only a cursory reference to the literature and did not include any of the relatively new conditions referred to above.

The most recent compilation by Felson and Heublein<sup>2</sup> of conditions that give rise to diffuse pulmonary lesions is therefore of considerable interest. These authors have classified the various conditions under fifteen separate major headings, such as cystic lesions, vascular, inhalation, infections, malignant lesions and embolization, with from two to as many as twenty separate diseases or conditions listed under each heading.

In spite of the length of this list, the authors admit that it is incomplete. Such conditions as Q fever, other rickettsial infections and amyloidosis, for example, have been overlooked. Their classification will, however, prove to be a very distinct aid in the evaluation of the various diffuse pulmonary lesions. These authors emphasize that it is hazardous to express an opinion of etiology solely on the basis of a single roentgenologic study. Even multiple examinations, which carry considerable weight because they allow for the evaluation of progression or retrogression, may not be absolutely diagnostic. However, as they point out, in a vast majority of cases correct interpretation can be accomplished after careful correlation of both roentgenographic and clinical studies but in a few cases the correct diagnosis will necessarily wait until autopsy.

associated with increased rates of nucleoprotein turnover. The literature contains at least 25 cases of polycythemia vera and gout, in addition to the 25 or more cases of leukemia and gout. There have been reported at least 11 cases of hemolytic anemia and gout, 9 cases of pernicious anemia and gout, many cases in which gout followed the hematoietic stimulus of blood loss and many more in which lead intoxication was the responsible factor. In pernicious anemia, the attacks tend to occur during the reticulocyte crisis induced by liver extract, at a time when nucleoprotein turnover is at its peak, and at least nine authors have reported induction of gout attacks by the injection of potent liver extract, not always in patients with pernicious anemia.

The most important observation suggesting that accelerated nucleoprotein turnover may be quite directly concerned in the production of gouty symptoms has been made in several cases of gout associated with hemolytic anemia. A number of these patients who have been submitted to splenectomy have been relieved of the symptoms of both diseases for follow-up periods up to ten years.

There appears to have been no study of the proportion of joint pains in leukemia that are actually referable to gout. Nevertheless, from a therapeutic point of view, recognition of this possibility appears desirable for the comfort of the patient, since gout attacks occurring during leukemia have responded to the judicious use of colchicine, the specific for the ordinary gout attack.

WILLIAM QUITMAN WOLFSON, M D

Michael Reese Hospital  
Chicago, Illinois

Dr Wolfson's letter was referred to Dr Mark Aisner, whose reply is as follows:

To the Editor Doctor Wolfson's letter brings up the interesting and, at the present time, highly controversial and speculative problems of nucleoprotein metabolism, hyperuricemia and gout, the inter-relations of which are still far from clear.

The commonest type of joint pain in the acute leukemias is polyarticular, often migratory, and clinically resembles most closely rheumatic fever and, in some cases rheumatoid arthritis. Although some patients present hyperuricemia, they do not show the typical features of gout. The fact that in many of the acute leukemias various changes in the bones and periarticular structures are demonstrated both roentgenologically and pathologically, none of which are seen in gout, may explain, in part at least, the symptoms of bone and joint pain in such cases. The age and sex distributions in the acute leukemias are quite different from those in gout.

The mere presence of hyperuricemia does not necessarily establish a diagnosis of gout. However, this finding, along with studies on uric acid excretion, has for years led to speculation regarding the relation between leukemia and its associated nucleoprotein breakdown and gout. Forkner, in his monograph *Leukemia and Allied Disorders* (333 pp New York Macmillan Company, 1938), comments that the "simultaneous occurrences of the two conditions is so rare that any real relationship seems doubtful." Statistically, the number of cases of true gout associated with the various disorders mentioned by Dr Wolfson is insignificant. Disturbances in nucleoprotein metabolism and hyperuricemia have been demonstrated in renal failure, toxemias of pregnancy, liver disease, lobar pneumonia, bronchopneumonia, arteriosclerosis with hypertension, cardiac failure, fatal methyl alcohol poisoning, chronic eczema and allied dermatoses and so forth. Yet gout remains a relatively rare disease so far as the frequency with which one encounters the disorders listed above is concerned. From a therapeutic standpoint the beneficial effects of colchicine do not help to clarify the relation between nucleoprotein breakdown and gout, since this drug has no apparent influence upon uric acid metabolism.

Although I agree that occasional cases of leukemia are associated with gout, I cannot subscribe to the idea that an appreciable number of them are.

In conclusion I should like to quote the statement of Peters and Van Slyke, that "when all is said and done the determination of uric acid in blood and urine still offers little aid to the clinician."

MARK AISNER, M D

## BOOK REVIEW

*The Diagnosis and Treatment of Diarrheal Diseases* By William Z. Fradkin, M D 8°, cloth, 254 pp, with 114 illustrations New York Grune and Stratton, 1947 \$6.00

This is a small, useful, clearly written and very well illustrated book, by a man with large experience in diarrhea as physician in charge of the Colitis Clinic and associate bacteriologist, Colitis Division, of the Jewish Hospital of Brooklyn.

It aims at being a short, practical presentation of laboratory and clinical features in the diagnosis and treatment of diarrhea. It has real value but might perhaps be compared to a hook on vomiting or headache. It is evidently addressed to the general practitioner as well as to the specialist in gastroenterology. Many of the methods of examination are too elaborate for the practitioner, and the book as a whole is much too short for the specialist. The value of a careful history is stressed, but one is not told how to use these data in differential diagnosis. The limitations and delay in stool cultures might be emphasized more. The chapter on intestinal parasites is excellent. In the excellent x-ray illustrations of ulcerative colitis, it is surprising to find the cecum sometimes on the right side and sometimes on the left side of the prints.

The general chapter on treatment is very good, but more detail could be given in some of the individual diseases. The results of treatment in cancer of the bowel are evidently considered beyond the scope of the book, being dismissed with half a line. The chapter on nervous diarrhea (four and a half pages) might be larger, since no organic cause is found in more than half the cases of diarrhea.

The author is evidently an individualist, and some of his statements might be misunderstood—for example, in ulcerative colitis, "surgery—is never indicated even as a partial aid in the management of this disease," "pregnancy should be interrupted in all patients" and "specialized psychotherapy is not indicated." Colectomy is not mentioned for this disease.

There is much that is good in the book, but much has been omitted because of the large field covered in a small volume.

## BOOK RECEIVED

The receipt of the following book is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

*Mental Health A practical guide to disorders of the mind* By John H. Ewen, F R C P E, D P M, physician and lecturer in psychologic medicine, Westminster Hospital, and medical superintendent, Springfield Mental Hospital, London. With a chapter on special treatments and their practical technique by C. Friedman, M D (Vienna), L R C P and S E d, registrar and tutor, Department of Psychological Medicine, St. Thomas's Hospital, psychotherapist, the Tavistock Clinic, and medical officer, Insulin Therapy Clinic, Springfield Mental Hospital. 8°, cloth, 270 pp. Baltimore: The Williams and Wilkins Company, 1947 \$4.00.

In Great Britain during the past few years, owing to the problems brought about by national planning and organization of mental health services, a knowledge of mental illness has become necessary to the general practitioner and social worker. This manual has been written to fill this need. Particular attention has been given to the requirements of students studying for a diploma in psychologic medicine. The text is divided into five sections. The first, which is general in character, deals with etiology, diagnosis and classification. The following sections in order consider the psychoneuroses, psychoses, mental deficiency and psychopathic states, and the legal aspects of mental disorder and mental-hospital practice from the British viewpoint. The material is well organized, and the volume well published. The printing was done in Great Britain. The manual should prove useful to those persons for whom it was written.

## MASSACHUSETTS MEDICAL SOCIETY

## IMPORTANT NOTICE

It is imperative that all fellows of the Society be properly classified as to their availability for military service when and if the occasion arises. The armed forces of the United States and the Council on Emergency Medical Service have requested that this be accomplished as soon as possible.

A return postal card has been sent to each fellow asking for certain pertinent information. This should be returned to the headquarters of the Society immediately.

H QUIMBY GALLUPE, M D, *Secretary*

## MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

## DIRECTOR OF DIVISION OF HOSPITALS

Dr Richard P MacKnight, former state director of hospital inspection, has been appointed director of the new division of hospitals of the Massachusetts Department of Public Health, Dr Vlado Getting, Massachusetts Public Health Commissioner, announced recently.

Dr MacKnight will direct the new division's activities, which include the inspection and licensing of hospitals, sanatoriums, convalescent and nursing homes, and boarding homes for the aged, as well as the administration of hospital survey and construction under Public Law 725 — the Hospital Survey and Construction Act.

Dr MacKnight has had a long and creditable career in public-health work, especially in relation to hospitals. After his graduation from Jefferson Medical College in Philadelphia in 1914, he served as rotating intern for twenty-eight months, and then entered the Army Medical Corps. He served for twenty-six months in World War I and attained the rank of Captain. After the war, Dr MacKnight went into private practice until 1923, when he was appointed assistant superintendent of the Bristol County Tuberculosis Hospital in Attleboro.

In December, 1924, Dr MacKnight became a district health officer for the Massachusetts Department of Public Health, and served in that capacity until 1938. He was appointed assistant director of the Division of Cancer and Other Chronic Diseases in 1939.

Dr MacKnight became supervisor of hospital inspection in 1942, he held this position until October, 1947, when he was further promoted to director of hospital inspection for the Massachusetts Department of Public Health. All this experience makes Dr MacKnight an excellent choice for the important work of the new division.

Until recently, hospital licensing and inspection had been handled by the Bureau of Hospital Licensing, under Dr MacKnight. The licensing of convalescent and nursing homes and of boarding homes

for the aged is a new function assigned to the Massachusetts Department of Public Health by the Legislature in 1948.

## MISCELLANY

## WATER POLLUTION CONTROL ACT

The Water Pollution Control Act (Public Law 84) has been signed by President Truman. Under the terms of this act a scientific program will be developed with federal loans to any state, municipality or interstate body for the purpose of pollution abatement and control. The program will be administered by the United States Public Health Service and the Federal Works Agency. The sum of \$112,000,000 will become immediately available for the first five year period.

## CORRESPONDENCE

## VETERANS ADMINISTRATION APPROVAL OF FOREIGN MEDICAL SCHOOLS

To the Editor: Dr J L Lochner, Jr, secretary of the Board of Registration for the state of New York, in his article in the May 1, 1948, issue of the *Journal of the American Medical Association*, entitled, "Licensure Evaluation of European Medical Graduates," calls attention to the fact that the Veterans Administration in Washington is advising veterans that they may attend any medical school in Europe at the expense of the Government. The veterans are furnished with a list of European medical schools that have been approved by the Veterans Administration, and, so far as Dr Lochner was able to ascertain, "named every single medical school abroad."

A committee on foreign medical credentials, consisting of representatives from the Association of American Medical Colleges, Federation of State Medical Boards, National Board of Medical Examiners, United States Office of Education, United States State Department and the New York State Education Department, is at work and is collecting valuable information about foreign medical schools and education. It is regrettable that the Veterans Administration has not consulted this committee and recommended to veterans schools that have been certified by the Committee.

It seems pertinent that the Massachusetts Medical Society should protest against the present policy of the Veterans Administration and that the Committee on Veterans' Affairs of the Massachusetts Medical Society should be requested to take up the implications of this policy with the Veterans Administration.

## BONE AND JOINT PAIN IN LEUKEMIA

To the Editor: The interesting discussion of bone and joint pain in leukemia by Drs Aisner and Hoxie in the May 20 issue of the *Journal* leaves the reader with the impression that most of these pains are nonspecific rheumatoid affairs. Actually, although it is not possible to obtain quantitative estimates, a review of the literature suggests that an appreciable number of joint pains occurring in leukemia may well be due to gout. Drs Aisner and Hoxie, for example, present data on a patient whose history of foot pain, acute arthritis in the elbow and a circulating urate level of 18.5 mg per 100 cc. is most suggestive of gout.

The rate of nucleoprotein turnover is known to be greatly accelerated in leukemia, as pointed out by Fortunato (11 *metabolismo dei nucleoproteidi nei leucemia Studi* 21 221-230, 1931) and by Wolfson et al (Transport and excretion of uric acid in man *J Clin Investigation* 26 995-1001, 1947). Although, on occasion, it has been suggested that an hereditary tendency is a prerequisite for the occurrence of gout in leukemia, most of the reported cases are sporadic. There is, in fact, considerable experimental and clinical evidence that the increased rate of nucleoprotein turnover is more than a mere inciting factor in cases of gout associated with leukemia. Gout may, for example, occur in other disturbances of hematopoiesis

## AMERICAN COLLEGE OF PHYSICIANS

The American College of Physicians will conduct its thirtieth annual session in New York City from March 28 through April 1, 1949. Secretaries of medical societies are especially asked to note these dates and, in arranging meeting dates of their societies, to avoid conflicts with the meeting, for obvious mutual benefits.

AMERICAN COLLEGE OF PHYSICIANS  
RESEARCH FELLOWSHIPS

The American College of Physicians announces that a limited number of fellowships in medicine are available from July 1, 1949, to June 30, 1950. These fellowships are designed to provide an opportunity for research training either in the basic medical sciences or in the application of these sciences to clinical investigation. They are for the benefit of physicians who are in the early stages of their preparation for a teaching and investigative career in internal medicine. Assurance must be provided that the applicant will be acceptable in the laboratory or clinic of his choice and that he will be provided with the facilities necessary for the proper pursuit of his work. The stipend will be from \$2200 to \$3200.

Application forms will be supplied on request to The American College of Physicians, 4200 Pine Street, Philadelphia 4, Pennsylvania, and must be submitted in duplicate not later than November 1, 1948. Announcement of the awards will be made as promptly as is possible.

EXAMINATION FOR MEDICAL-OFFICER  
POSITIONS

The United States Civil Service Commission has announced an examination for filling medical-officer (rotating intern and psychiatric resident) positions in St. Elizabeths Hospital, Washington, D. C.

Medical officers (rotating intern) are paid \$2200 for the first year and \$2400 for the second year. Medical officers (psychiatric resident) are paid from \$2400 to \$4100 a year, depending upon the amount of approved postgraduate training the applicant has completed. Appointments are open for July 1, 1949. Internships consist of two years of rotating service, and psychiatric residencies consist of one to three years in psychiatry. To qualify for internships applicants must be third-year or fourth-year students in an approved medical school, however, they may not enter on duty until they have successfully completed the full course of study. Applicants for psychiatric residencies must be graduates of an approved medical school, with the degree of doctor of medicine, and, in addition, they must have completed an approved internship or must be serving such an internship. No written test is required for the medical-officer positions. Details about the requirements are given in the examination announcement.

Interested persons may obtain information and application forms from the United States Civil Service Commission, Washington 25, D. C., from most first-class and second-class post offices and from Civil Service regional offices. Applications will be accepted until further notice in the Commission's Washington office.

THIRD INTER-AMERICAN CONGRESS OF  
RADIOLOGY

The third Inter-American Congress of Radiology will be held in Santiago, Chile, on November 11, 1949.

UNITED STATES NAVY MEDICAL  
TRAINING PROGRAM

The Surgeon General of the Navy has announced the expansion of the professional training program of the Bureau of Medicine and Surgery for reserve and regular medical officers, which is similar to the recently expanded Army medical training program. The object is to permit more Navy doctors to meet the requirements for certification by

the various American specialty boards and to enable the young doctor to serve his internship under the auspices of the Navy.

Graduates of Class A medical schools who have been accepted for internship by a hospital approved for such training by the Council on Medical Education and Hospitals of the American Medical Association may be commissioned as lieutenants (junior grade), MC, U. S. N. R., and permitted to continue their intern training. They will receive all the pay and allowance of the rank while so serving. After completing their internships, the medical officers must remain on active duty for a period of one year. If they meet the professional, physical and moral requirements, they will be given every encouragement to transfer to the regular Navy.

Interns who have completed the one year of obligated service, and who have transferred to the regular Navy, may be considered for residency training on a competitive basis with other officer personnel of the regular Medical Corps.

Resident physicians now in civilian hospitals, or those accepted for approved residency training, are eligible for commissions in the regular Navy. Those so commissioned will be assigned to duty, with full pay and allowances, in the hospital in which they are already a resident, or to which they have been accepted for residency training. Every attempt will be made to permit residents holding commissions in the regular Navy to complete their training in event of an emergency.

The Navy has at the present time 400 approved residencies and fellowships in the various specialties recognized by the American Specialty Boards in Navy and civilian hospitals. This educational training involving the 400 residencies is divided into 2 programs.

**Program A** One hundred of the above mentioned residencies, courses and fellowships will be made available for civilian physicians accepting a commission in the United States Navy. An additional 100 civilian physicians will be commissioned in the Navy and permitted to pursue their course, fellowship or residency, provided it is approved by the Council on Medical Education and Hospitals of the American Medical Association with concurrence of the specialty board. Upon acceptance of the designated training, they will be required to agree to remain in the Navy for a certain obligated time.

If on original appointment a candidate has not been approved for more than one year of training, during his first year of residency training (Program A) he may compete for one of the 300 residencies (Program B) available to the regular Navy medical officers, and if he obtains such training he will obligate himself to remain on active duty for an additional period depending upon the amount of time spent in training.

**Program B** Three hundred residencies, fellowships or courses, will be reserved for continuing the training program as presently organized for regular medical officers.

The obligated service following graduate medical training (courses, fellowships and residencies) in Navy hospitals is one year for each year of training received.

Information concerning any part of the program may be obtained by application to the Chief of the Bureau of Medicine and Surgery, Navy Department, Washington 25, D. C.

## A REPORT TO THE NEW ENGLAND SURGICAL SOCIETY CONCERNING THE AMERICAN BOARD OF SURGERY\*

SAMUEL C HARVEY, M D †

NEW HAVEN, CONNECTICUT

THE American Board of Surgery, established in 1937, has completed the first ten years of its activities. It seems appropriate that the present representative on the Board of the New England Surgical Society should report upon its accomplishments and the lessons learned during this time.

It is best, perhaps, to start with the reasons for its establishment. These were in general two: the chaotic situation regarding the qualifications that might reasonably be expected of a surgeon, and the inadequacy, both in quantity and in quality, of opportunities for obtaining the experience necessary to prepare one to meet these qualifications.

It was generally recognized at that time by those competent to judge that a large component of surgery was done by inadequately trained physicians devoting only a part of their time to this specialty. It was well nigh impossible to ascertain except by personal knowledge, not generally available and frequently unreliable, who was in fact a competent surgeon and who was not. In the *Directory of the American Medical Association* surgeons were authenticated on their own statements that they were practicing surgery and therefore presumably competent. In fact, it was generally known that a great many physicians in general practice were doing their own surgery even in communities where competent surgeons, confining their practice to surgery alone, were available.

This situation had been recognized and discussed for many years, and several solutions had been proposed and some attempted. Governmental licensure of specialists had been repeatedly suggested but was obviously impracticable if not undesirable, for this could only be accomplished by legislation in each of the states, a procedure that has not been satisfactory enough, when applied to the basic requirements for the practice of medicine in general, to encourage its application to the specialties.

Membership in surgical societies was, with the exception of the surgical section of the American Medical Association and the American College of Surgeons, a mark of distinction too limited in its coverage. In the former one joined on signifying an interest in surgery, and in the latter the requirements were on a level pitched at initiating men actually doing surgery with the hope of improving their competency through postgraduate education.

The pattern of the boards for certification has become well established in other specialties, and that of surgery, a latecomer in the field, was set up along the same lines, being approved on the recommendation of the Advisory Board for Medical Specialties, by the Council on Medical Education and Hospitals of the American Medical Association. It should be made clear that, while recognized in this fashion, the American Board of Surgery was the result of the thought and action of many informed surgeons recognized by their colleagues as such, and approved by the major representative surgical associations, this has been evident in the continuing organization and functioning of the Board.

The objectives of the Board were and are to examine applicants and certify those meeting its requirements and — a purpose inextricably interwoven with this — to improve the opportunities for the training of surgeons by establishing the qualifications necessary for examination.

As in other specialty boards, the first certificates granted were to members of the founders' group "who had already amply demonstrated their fitness as trained specialists in surgery," 1152 surgeons being so certified. These were the senior surgeons to whom it would have been a hardship, if not an impossibility, to take the examinations. This method of admission could not be continued indefinitely without vitiating the purposes of the Board, and therefore it was announced at the start through suitable channels that the founders' group would be closed as of January 9, 1940. Unfortunately, for one reason or another, a number of sur-

EVANSVILLE, INDIANA, U.S.A.

aspect — and they are by no means immune to the charge of exploitation of professional personnel at his level — can be more adequately and readily done, for they are fewer in number and more susceptible to investigation both in potentiality and in performance

This screening of the applications is, then, the first step in the process for examination and a very necessary one, not only for the purposes of the Board but also for the best interests of many candidates. Some say that all who wish should be admitted to the examination without further ado. The result of this would be that either a large number of candidates would be failed or so many would pass that the Board would be discredited as an examining agency. To avoid the latter it would then tighten up its examination, failing some men who do not do well on the examinations, but have had good training, and passing others skilled in taking examinations, but who have had little or no experience. Less important perhaps is the number who would take a "flyer" at the examination on the chance of slipping through and would make it almost impossible to handle the load. Lastly, a major purpose of the Board, that of encouraging the development of adequate training programs, would be under these circumstances completely vitiated. This suggestion of relying completely upon examination is advanced by those who have not thought the question through or who suppose that this procedure is or can be made one of great accuracy. The methodology of examination has been thoroughly studied by experienced workers in the field of education and it has been well established that as the sole source of reference it has a considerable degree of error — approximately 20 per cent. The expression of results in precise mathematical terms gives an appearance of absolute and accurate value that is fictitious. It is at best only an approximation and must be reinforced in every way to reduce the error so far as possible, one of these is to evaluate the opportunity that the candidate has had for learning in the field of surgery.

This evaluation is made in the first instance by the secretary of the Board, whose long experience and sympathetic insight into the problems of the prospective surgeon are invaluable. In instances in which the problem is at all complicated, or in which his decision is questioned, the matter is carried before a special committee of the Board for further consideration and adjudication. Although the interests of the applicant concerned are viewed sympathetically and in detail, the paramount responsibility of the Board is to the public and its decisions must be so governed.

Another knotty problem concerned in the screening process is that of the ethical and moral standards of the candidate or, as I should prefer to put it, the pattern of behavior that may be expected of him in his future professional life. This has no reference

to economic and social classification, race, creed, color or sex, because the pattern of behavior is not conditioned by these, per se, although as in all persons, adversity and misfortune may have a warping effect. It is the right of one in our form of civilization to be considered an individual rather than to be submerged in invidious categories. The record of the Board in this respect is one of which all surgeons may well be proud.

This "pattern of behavior" is unpredictable to a considerable degree even with adequate information. The usual letters of recommendation are perfunctory, sometimes even mendacious, and these sources of information are, on the whole, not reliable. They are worth obtaining, however, because of the occasional enlightening response, which may lead to further investigation. When there is any cause for suspicion certain persons whose reliability is beyond question are queried confidentially. This necessity may arise when a man has shifted about for no apparent reason. Without evidence to the contrary, it may be assumed that the behavior of a person who completes his training in one institution, or in several, with a sense of responsibility has been above reproach, at least up to that time. In spite of these precautions it is not only possible but probable that there are a certain number of certificated surgeons whose practice will be tagged "unethical." Occasionally this complaint comes to the Board, and it is taken most seriously. When the evidence justifies such a step, certification is recalled, but it is necessary to be certain that it will stand up in court, for it is likely that legal action for damages will be taken against the Board. In the majority of cases on detailed inquiry it is found that there is an internecine situation — one of those professional quarrels arising from jealousy, clash of personalities and so forth and giving rise to charges of "unethical conduct" that even locally are never taken so seriously that they are brought before a board of censors of the county or state society. Frequently it is a stab in the back of which the victim is unaware, for the informer insists on remaining anonymous. I dwell on this not to establish a thesis that the Board makes no errors in the evaluation of the future behavior of men accredited by it, but to call attention to the inherent difficulties in this problem. If the New England Surgical Society or any other organization can see its way clear to being of assistance to the Board in this matter it will be welcomed.

The examination having taken place, every effort is made to obtain a fair evaluation of the results. In the written examination (Part I) the papers of all failures or near failures are reviewed by two additional members after the initial reading by a member of the Board, and the mark primarily given confirmed or revalued. Papers that are still doubtful are brought before the Board as a whole and fully discussed with the additional information concern-

geons at the time presumably qualified, did not see fit to take advantage of this opportunity. Even more unfortunate, in spite of ample publicity concerning the requirements of the Board for examination, a group of younger men were unable or at least did not make any attempt to fit themselves to meet its basic requirements. To lower these requirements now to meet the desires of these men would be unfair to those who have spent the necessary time and energy to prepare themselves properly and would encourage others to attempt a similar short cut to certification.

Meanwhile, during the first ten years of activity of the Board, 1752 surgeons were certified by examination, making with the founders' group a total of 2904. As of January 1, 1948, there were 2062 and 3214, respectively, 310 having been certified by examination during the past year.

It is of interest to you, I am sure, to get some idea of the activity that is involved in this examination process. During the year 1946 the Board had about two thousand letters of inquiry. There were 789 completed applications, of which 40 per cent were at once acceptable for examination. Others may have become so with further information or preparation, the general experience is that only about 20 per cent of the completed applications are finally rejected. Out of some 700 men taking Part I of the examination, of whom 100 were repeaters, 25 per cent failed. Of 362 taking Part II approximately the same percentage also failed. It should be borne in mind that these data for Part II comprise numerous partial failures and that the actual number of final failures is somewhat lower because of success when the candidate repeats the examination.

The criteria that are used for the process are relatively simple, and at the same time reasonably rigorous. The candidate must demonstrate that he has a sound knowledge and understanding of the field of general surgery as of today. This is in part contained in the more detailed texts of general surgery, and in the surgical literature of the last ten years, which may not yet have arrived at this distinction. He must also give evidence that he is capable of employing this knowledge with judgment and skill in the care of the patient. The question always asked in summation is, "Is this potentially a safe and sound surgeon?" Such values are, of course, relative, as is the process of examination. Thus, it must be considered as a screening mechanism in which the sound and unsound grain, together with a considerable amount of chaff, go into the original hopper.

The review of the application is the first screen, and is concerned with whether the candidate has had a fair opportunity to learn through study and experience what the surgeon entering upon practice today should know, a matter requiring adequate exposure to both time and environment. This cannot be and is not rigidly defined and enforced, but one must bear in mind that no matter at what level

the bar is set there will always be some who will insist upon attempting to crawl under it, even if the same amount of exertion expended properly would enable them to clear the obstacle without difficulty. The judgment of the Board has always been that a minimum of three years of institutional training is necessary, supplemented by two years of further experience. Recently, this has been modified upon the basis of experience indicating that one year of additional institutional training is usually equivalent to two years of supplementary experience gained otherwise. Therefore, four years of continuous, graded, institutional training is now recognized as adequate for admission to examination. It is the opinion that this represents the more desirable approach, but the number of opportunities for this intensive training are limited, and quite aside from the question of desirability it will be necessary for some time to continue also the requirements as established previously — namely, three years of institutional training with two years of supplementary program. There are thus two plans in effect by which a man can obtain the necessary preparation before taking the examination of the American Board of Surgery, one requiring five years, and the other four.

One may well ask whether the former is not quite satisfactory and what experience of the Board has led it to an adverse conclusion. The two supplementary years are almost as difficult to obtain as the additional year of institutional experience and often amount to little more than a waiting period, the educational value being only that which the prospective surgeon may vicariously gain in the first two years of practice. It is becoming increasingly difficult for him to obtain the hospital facilities necessary for surgical practice until he is at least eligible for examination. This fact, as well as the necessary requirement of the Board that he show evidence of further experience under suitable conditions, forces him into the hands of a preceptor. This relation may, when the preceptor is himself competent and also interested in the active and progressive training of the man, be highly desirable. Unfortunately it is altogether too frequently the subject of abuse, and the young surgeon becomes the preceptor's assistant with inadequate remuneration and the experience that is acquired in doing the "scut" work for the older man. He may then find, having completed his period of service, that any attempt to establish himself in practice is blocked at every turn by the very man who has been his preceptor. I cannot conceive that any surgeon will in principle condone conscienceless exploitation, and certainly the American Board of Surgery cannot be a party to any such business. Yet, under present conditions and despite the exercise of the greatest possible caution, this situation may inadvertently arise in occasional cases. On the other hand the evaluation of institutions in this

ive been established. These are particularly important as "pilot plants" for working out and demonstrating the proper approach. There are, however, by no means enough of these hospitals to train an adequate number of surgeons to replace those daily dropping by the wayside. Unfortunately, the idea has developed that without the facilities of a school of medicine it is impossible to carry out such training programs. This is not the case, and if the objectives projected in the formation of the Board of Surgery are to be achieved, many hospitals that are potentially capable of undertaking this training must do so. If the hospital is situated so that it is possible to do this under the guidance and with the assistance of a school of medicine, it may be the more readily accomplished, but this is not essential. There are now a sufficient number of younger surgeons who have been through this process of examination and training and who are therefore familiar with the concept and the application of it, so that given the opportunity this conversion of many hospitals quite away from schools of medicine and institutions for formal graduate instruction can be accomplished.

There are some who question the need or appropriateness of this method for the training of surgeons. To some it may seem an "academic" approach directed at the provision of the future teacher, rather than a "practical" method for obtaining practicing surgeons. If this is true, it has failed completely, for much more is required of the professional teacher than is provided in this program. More time and greater breadth of experience, particularly in the technics of teaching and investigation, are necessary for him. The requirements of the present training program, I must repeat, are directed at training competent, sound surgeons.

Another question that may be proposed is, Has the Board been reasonably successful in attaining its objectives? I think that there can be no question of the answer. The degree of recognition that has been accorded its diplomates has even proved embarrassing. The armed forces and the Veterans Administration, without the previous knowledge of the boards, recognized the qualifications of those physicians and surgeons who were diplomates, not only of the American Board of Surgery but of all the other specialty boards. That they were justified in so doing was proved by the experience during the war, for when these men were given appropriate assignments they performed superbly. In the Veterans Administration at the moment they are the core and foundation of the hope for improved professional care. Again, I wish to emphasize that the preferential position that these diplomates hold is not by any action of the boards, but is a voluntary and unsolicited recognition of their superior qualifications.

A similar situation for which the Board is not responsible is the special recognition of the diplo-

mates accorded by many hospitals. This is not the concern of the American Board of Surgery except so far as the indiscreet, injudicious and arbitrary action of many of these institutions has served to throw discredit upon it. It has officially and in all honesty disclaimed any responsibility for this. Many hospitals have made a very laudable effort to elevate the level of professional services and have considered a blanket and complete restriction of facilities to certified specialists the simplest and most effective way of doing so. They have overlooked in many cases the fact that such an abrupt transition cannot be made. There may be on their staffs men who are known to be incompetent and whom they justifiably wish to dispossess. The easiest way, instead of deciding and acting in the individual case, is a blanket ruling requiring certification for staff membership and thus relieving themselves of the personal antagonism aroused by direct action. Unfortunately, this also dispossesses many surgeons who in their services have long since proved their competence, but who because of age fall in the intermediate group caught in this transitional period without certification. In doing this, the hospital "throws out the baby with the bath." In all fairness, although the ultimate transition in many hospitals may well end in making their facilities available for the most part only to those certified, such a regulation is at present premature. In fact, in some situations it may be a long time before this can be done, for there is still an inadequate number of diplomates to fill the needs, and in many of the smaller communities it would be an economic impossibility to support these specialists were they available. The objective, although it may be admirable, cannot be reached at once and in all cases, but must be approached by a period of transition and adjustment.

It is my impression, and that of many others, I am sure, that the success of the Board's activities has been well beyond what the originators of it might reasonably have expected. It has by no stretch of the imagination resolved the problem of providing a high grade of surgery for all, and there still remains a very great and disgraceful amount of incompetent, dangerous and unnecessary surgery. Recently, at a meeting in New York of the American College of Surgeons, Dr. Harold L. Foss pointed out what all of us know but rarely confess. This has received considerable publicity and will intensify the pressure upon the hospitals for restricting the specialists within them to those who are diplomates of their respective boards. This is a problem that the members of the New England Surgical Society might well study, for it is to them that the public should look for a proper answer. The Board cannot do this, it can only assist in the carrying on of its specific functions. It is not in any sense responsible for the development of a postgraduate plan of education, or of surveying and making

ing the candidate that may be pertinent, and the Secretary is directed regarding suitable action.

In the oral examination (Part II) held in clinical surgery on patients, in anatomy on the cadaver and in pathology on gross surgical specimens and microscopical sections carefully selected, approximately half the examiners are surgeons other than members of the Board and competent for this purpose. In clinical surgery teams are made up of a Board member and an accessory examiner who query together and separately grade the results. Since the candidate has two cases for examination, he is evaluated by two teams, a total of four surgeons, two of whom are Board members. This part of the examination is rated heavily, but there is also insistence that he demonstrate a knowledge of anatomy and pathology, adequate for sound surgery. This requires intensive study or review by most candidates, for it is the experience of the Board that men otherwise competent are frequently distressingly lacking in these subjects, which are fundamental to surgery.

The evaluations so obtained are assembled and gone over in a conference of all examiners in which questions and discussion are most welcome. With the failures and in doubtful cases, the information available in the secretary's files is brought to bear before a decision is reached, and then the Secretary is instructed concerning the action to be taken. It should be noted that in this conference, which is the last and most important step leading to certification, while the members of the Board bear the responsibility, they are assisted by an equal number of surgeons who are not Board members. This has the advantage of relieving it of any implication of bias and bringing into its activities at the most significant point a considerable number of surgeons who not only contribute materially to its deliberations but also learn at first hand the way in which the Board approaches this problem of examination and certification.

The second purpose is the improvement of the training of surgeons who may wish to qualify for the certificate of the Board. As pointed out above, the first and, as has been confirmed by experience, the most important step was taken when the general plan of training was outlined. This was made sufficiently rigorous in the over-all requirement to ensure the necessary time and application for the learning of surgery, but elastic in detail so that the candidates' individual ability and opportunity would not be forcibly compressed into a standard form. Unfortunately, as educators are well aware, the majority of students "jell" into a pattern if there is the slightest opportunity to do so, and it is almost traditional, as well as being consistent with human nature, that some will attempt to find some way of "beating the game." There is too much of the idea that the awarding of a certificate makes a surgeon, a fallacious concept that is by no means limited to the experience of the American Boards of Surgery.

For these candidates, the requirements must be rigorous, and vigilance must be constantly employed to see that in one place or another the standards are not evaded. For others, and fortunately there are many of these whose primary and fixed interest is in becoming sound and competent surgeons, great elasticity is allowable. The touchstone is whether the primary interest lies in the certificate or in the antecedent training. This can be ascertained fairly readily in most instances by the plan that the candidate submits for review, if he does not submit such a plan to the Board, it must assume that he is content with the customary pattern and is not concerned with its being adapted to his particular desires or opportunities.

A problem that remains a distressing one is the lack of suitable institutions both in quality and quantity capable of providing the opportunity for learning to be a surgeon. This has always been apparent and was recognized in 1936 by the American College of Surgeons when the regents adopted a policy directed toward increasing suitable residencies. So far as physical facilities, proper administration and organization, number of patients and competent surgeons on the staff are concerned, there are plenty of hospitals that could and should undertake the responsibility for training surgeons. But there is more to it than this, and this centers about a willingness of the professional staff to modify certain prerogatives and to divert a modicum of time and energy to a program directed at training surgeons. There must be a continuity of effort and maintenance of its operation at a constant high level, which requires that one person—a surgeon—must have the responsibility and the authority for carrying this on. When there is already an authoritative chief surgeon, he must in addition be competent, familiar with the literature, soundly educated and have a great interest in teaching in the broadest sense. To do this, he and the staff will have to sacrifice some of their customary activities, however, if a sound residency system is established, any concessions made by the staff will be more than compensated for by the assistance and stimulation of these younger men. Lastly, there comes a time when direct responsibility for the complete care, including operative procedures of an adequate number of patients, under supervision, of course, provides the final step in training. This seems to involve the greatest difficulty in the organization of the complete training program, particularly today when private patients are consuming bed capacity, leaving but few in the ward category. If one thinks of the resident at this stage of his development, at least four years out of medical school and with three years of surgical training, as a "junior attending" surgeon who is incidentally living in the hospital, the transition is less difficult.

In many hospitals connected with the schools of medicine such residency-training programs

low include all lots used during the past twelve months, but the similarity of their composition, spite several minor changes, makes a statistical valuation valid. In Table 1 the composition of a representative lot of the solution of amino acids with respect to the eight amino acids essential for man\* and for arginine and histidine is shown and is compared with that of casein. The results are based on analyses by microbiologic assay.<sup>7-9</sup>

All subjects selected were carefully followed each day. Many of the infusions early in this study, as well as subsequent ones, were given to subjects in the metabolic ward for more detailed study. Since this product had previously been shown to be well tolerated in dogs at very rapid rates of in-

tients received this product postoperatively as the sole source of protein, as did the newborn infants with infectious diarrhea. The patients with malnutrition and liver disease usually received the amino acid solution as a parenteral protein

fusion,<sup>1,2</sup> it was planned to administer it at rates exceeding those possible with the commercial protein hydrolysates that had previously been employed. In no case was the rate of infusion slowed to avoid or diminish a reaction. The following data were obtained: the diagnosis and body weight, quantity of material infused, quantity of other substances (glucose, vitamins and so forth) simultaneously infused, time required for infusion, and all untoward reactions, both immediate and delayed, no matter how mild or transient.

## RESULTS

### Classification of Subjects

The subjects were classified by diagnosis (Table 2). We were able to observe the most minute untoward effects in the normal volunteers (medical students and interns) even at extremely rapid rates of infusion (50 gm. of amino acids injected intravenously in ten minutes). Similar data were obtained from the convalescent patients. All other subjects were infused for therapeutic reasons as well as for data concerning tolerance. Most of the surgical pa-

supplement. Many of the patients were critically ill.

### Quantity of Material Administered

The quantity of the 10 per cent solution of amino acids administered with each injection is shown in Table 3. Dosages of 30 cc (3 gm. of amino acids) of the solution were given twice daily with an equal volume of 10 per cent dextrose to newborn infants with infectious diarrhea. This actually amounts to over 0.5 gm. of protein per kilogram of body weight at each injection and is roughly comparable to the injection of 500 cc (50 gm. of amino acids) to a 70-kg adult subject. All the 342 injections in this study were given in thera-

peutic amounts — that is, they supplied at least 0.5 gm. of protein per kilogram of body weight, and many were larger.

### Composition of Material Administered

When administered for therapeutic purposes on the hospital wards, particularly when employed as the sole source of protein nutrient, the 10 per cent solution of amino acids was frequently given with 5 to 15 per cent dextrose in water or physi-

recommendations to hospitals regarding the organization of their staffs. It is not a continuing organization. When the man receives his certificate he does not become a member of a group such as this, or the American College of Surgeons. There is a place, however, for the postgraduate continuing education of the surgeon, a function that surgical organizations may perform and, particularly on a national scale, the American College of Surgeons is splendidly organized to carry out.

Quite aside from this, the New England Surgical Society can assist the American Board of Surgery in its objectives of improving the training of surgeons and of examining those who have had adequate training. Beyond this there are certain needs apparent from the previous discussion. The necessity for more hospitals that can give acceptable

residency training is great, and the members of the society should take the initiative and responsibility in developing their institutions to this end. Information—candid and dependable—regarding hospital staffs in respect to teaching programs and applicants who may apply for admission to the examination is sorely needed and could be provided in New England by the members of this society. Thoughtful criticisms and suggestions are always welcome to the Board and can be readily presented through representatives of the Society. Above all is needed the moral support of the members if the Board is believed to be doing reasonably well while the Society endorsed in the beginning and what its representatives have attempted to carry out in conformity with its wishes.

## THE RAPID INJECTION OF A SOLUTION OF AMINO ACIDS

### A Note on Its Clinical Tolerance in Man\*

RICHARD D. ECKHARDT, M.D.,† AND CHARLES S. DAVIDSON, M.D.‡

BOSTON

**E**XPERIENCE with the parenteral administration of protein hydrolysates of five varieties (four acid and one enzymatically hydrolyzed) has led us to establish certain criteria for an ideal solution. In the first place, it must be shown to be nutritionally adequate by maintaining weight and nitrogen balance in the normal person when used as a sole source of nitrogen, and, in addition, positive nitrogen balance, weight gain and regeneration of serum albumin should be observed in persons depleted of protein. Secondly, side effects—that is, pyrogenic reactions, nausea, vomiting, venous thrombosis and anorexia—should be minimal. Thirdly, the solution must be nonantigenic. Finally, only small amounts of the material injected should appear in the urine, even with rapid infusion. Although the available hydrolysates have been shown to be nutritionally adequate as measured by nitrogen balance, unpleasant side effects occur frequently enough to limit their clinical usefulness.

Observations of the clinical tolerance to a 10 per cent solution of amino acids§ prepared by the re-

combination of fractions of an acid hydrolysate of casein are reported below. The solution is essentially devoid of glutamic and aspartic acids, and supplemented with dl-tryptophane and glycine.<sup>1</sup> The results of 342 injections in 62 subjects over the past year indicate that the present solution of amino acids is better tolerated in man than the previously employed. The nutritional adequacy of the material and the urinary loss following infusion will be reported subsequently.

### MATERIALS AND METHODS

The product under investigation is a complete acid hydrolysate of casein, contains no peptides, is essentially devoid of the dicarboxylic amino acids (glutamic and aspartic) and is supplemented with dl-tryptophane and glycine so that it contains the eight amino acids essential for man.<sup>2</sup> Additional dl-methionine was added to the product employed in our early studies, but is no longer supplied since excess methionine in man does not contribute nutritional advantage to a protein containing adequate quantities of this amino acid.<sup>3,4</sup> The solution of amino acids now regularly contains adequate phenylalanine, although some of the early lots contained an insufficient amount of this essential amino acid.<sup>5</sup> The product is now neutralized with lactic acid to a pH of 7.2 to 7.4, whereas hydrochloric acid was previously used. Observations of the clinical tolerance of the 10 per cent solution of amino acids in man reported

§Developed and distributed by Merck and Company Inc., Rahway, New Jersey, who supplied the material used in this investigation.

was more apparent in individual cases. Some subjects tolerated 50-gm amounts but became nauseated with 100 gm, even at a slower rate of infusion. Although nausea was noted in 27.4 per cent of the subjects at one time or another during the period of therapy, it occurred in but 9.4 per cent of all injections. Of the 17 subjects who became nauseated during this study, 9 (53 per cent) accounted for 75 per cent, and 3 (18 per cent) for 37.5 per cent of all cases of nausea observed. It appears, therefore, that the nausea that followed this solution of amino acids was not definitely related to the speed of the infusion (and thus the height of the blood amino acid level) but, to some degree, to the quantity of material infused (apparently a "saturation" phenomenon), and, most of all, it appeared to be an individual reaction most frequently observed in a few subjects.

Since no infusions were slowed down to lessen reactions, the severity of the nausea can be judged by the end point of vomiting. In only 2.6 per cent of all infusions did vomiting occur. In 4 of the 9 cases it followed an attempt at forced feeding, and in another it followed the ingestion of brewer's yeast immediately after the infusion.

The true incidence of anorexia is probably higher than the 9.1 per cent observed, since this phenomenon was not always inquired about and some patients were tube fed or too ill to be aware of such a subtle subjective reaction. It is our impression, arrived at mainly from normal subjects, that a transient diminution of appetite usually occurs but is of very short duration and rarely persists for more than one or two hours. Two subjects studied on our metabolic ward received the solution of amino acids parenterally for nineteen and twenty days, respectively, and consumed at least 3000 calories of food by mouth at regular meal hours. Thus, with the infusion speeds readily attained with this product, proper spacing of the infusions between feedings allows for normal food consumption at the regular mealtimes.

In approximately 7.6 per cent of all injections, and in 21.0 per cent of all subjects, a transient sense of "flushing" or "warmth" without temperature change was noted. There was no significant change in the blood pressure in several subjects in whom this observation was made. In 3 of the 62 subjects (4.1 per cent) and in 5 of the 342 injections (1.5 per cent) an urge to move the bowels immediately after the infusion was noted, occurring only with rapid rates of infusion. A few subjects complained of a mild frontal headache. On careful questioning, several subjects were aware of the ability to "taste" and to a lesser extent to "smell" the infusion immediately after it had entered the vein. This sensation was transient. A very few subjects noted mild formication of the extremities.

The veins of all subjects infused with this solution were carefully watched. No cases of venous

spasm, as has been reported with amino acid infusions,<sup>10</sup> were noted even with the rapid rates of infusion. Of the 342 infusions, thickening of the vein wall occurred in 8 (2.3 per cent). In 2 subjects the thrombotic process appeared to be inflammatory, the redness appearing about one day after the infusion and subsiding after about twenty-four hours. In these cases there was complete occlusion of the vein. Although glucose (even in hypertonic solutions) was frequently given with the 10 per cent solution of amino acids, no in-

Average			9.4

\*No objective reactions were observed in the 90 injections in the newborn infants with infectious diarrhea.

creased incidence of thrombosis could be attributed to its use. Many subjects received multiple injections of this solution in the same vein, and thrombotic processes developed in only 4 of the entire group.

When a diuresis occurred it could be related to the quantity of fluid infused. One patient with rheumatic heart disease with mitral stenosis and another patient with multiple pulmonary and mediastinal metastases from an osteogenic sarcoma became short of breath during the infusion, but to no greater degree than when an equivalent quantity of fluid containing dextrose and water was given. Obviously one must employ discretion whenever solutions are administered parenterally to patients with diminished cardiac reserve. No anaphylactic reactions of any type were noted — and, indeed, none were anticipated since the product is a complete hydrolysate and does not contain peptides. Clinical acidosis was not apparent, even on repeated daily injections. No untoward reactions were observed in the 90 injections in 7 infants with infectious diarrhea of the newborn. Finally, no serious reactions or deaths due to these 342 injections in 62 subjects were observed.

## DISCUSSION

The 10 per cent solution of amino acids employed in this study had previously been shown by others to maintain weight and nitrogen balance in normal dogs<sup>11</sup> and to achieve positive nitrogen balance with regeneration of hemoglobin and plasma proteins in the doubly depleted Whipple dog.<sup>12</sup> The results obtained in the present study of the clinical

ologic saline solution. Vitamins prepared for parenteral use (B complex, C and K) were often added. Many of the malnourished group and patients with cirrhosis of the liver received 10 to 20 cc of

crude liver extract\* in the infusion mixture. Sodium lactate was occasionally added. On three occasions the solution of amino acids (50 gm) was given

ing the solution diluted to a large volume administered by constant intravenous drip. Over 70 per cent of the 342 infusions administered to our 62 subjects were given rapidly—that is, at rates corresponding to the infusion of 50 gm of amino acids to a 70-kg subject in less than an hour. Seventy-one per cent of these 242 rapid infusions were given at the rate of 50 gm of amino acids to a 70-kg subject in thirty minutes or less, and 41 per cent similarly in a quarter of an hour or less. These rates of infusion were far more rapid than could be attained with any of the protein hydrolysates previously employed, and at least four times faster than is usually recommended that they be given—that is, 50 gm of amino acids to a 70-kg adult in two hours.

### Reactions

The incidence of reactions at varying rates of infusion is presented in Table 5, and that of reactions

‡Percentage of reaction for each rate period.

together with 75 gm of human serum albumin (300 cc of a 25 per cent solution). Although 240 of the 342 injections were "mixed," there was no apparent difference in the clinical tolerance whether the solution of amino acids was given alone or with these other substances. The only noticeable effect of the addition of other substances to the solution of amino acids was the decrease in the infusion rate necessitated by the increased fluid volume.

### Number of Injections per Subject

Although many of the subjects received multiple injections (Table 4), no apparent increased incidence of untoward reactions was observed with subsequent infusions.

### Rate of Infusion

In Table 5 are presented the rates of infusion of the solution of amino acids employed during this study. Only 7 per cent of all injections were given slowly, and most of these were in patients receiv-

ing the solution diluted to a large volume administered by constant intravenous drip. Over 70 per cent of the 342 infusions administered to our 62 subjects were given rapidly—that is, at rates corresponding to the infusion of 50 gm of amino acids to a 70-kg subject in less than an hour.

Seventy-one per cent of these 242 rapid infusions were given at the rate of 50 gm of amino acids to a 70-kg subject in thirty minutes or less, and 41 per cent similarly in a quarter of an hour or less. These rates of infusion were far more rapid than could be attained with any of the protein hydrolysates previously employed, and at least four times faster than is usually recommended that they be given—that is, 50 gm of amino acids to a 70-kg adult in two hours.

should have anticipated from the infusion bottle and sets employed.

Nausea was observed in 9.4 per cent of all injections, and did not greatly vary in incidence with the rates of infusion. There does seem to be a greater incidence of nausea, however, the larger the quantity of material injected (Table 7). The increased incidence of nausea with larger infusions

## THE AGE DISTRIBUTION OF POLIOMYELITIS IN MASSACHUSETTS

R. J. M. HORTON, M.D.,\* AND A. DANIEL RUBENSTEIN, M.D.†

BOSTON

DATA concerning the incidence of poliomyelitis in Massachusetts have been collected by the Department of Public Health since 1907. This material had been studied statistically by Forsbeck and Luther<sup>1</sup> in 1930, and it was thought that a review of these older records, combined with the

consideration of the age distribution. The material on the geographical aspects will be published elsewhere.

In the earlier study of Forsbeck and Luther,<sup>1</sup> it was noted that the percentage age distribution of the reported cases of poliomyelitis had been undergoing considerable variation. This change,

data accumulated during the past fifteen years would yield additional information on this subject.

In the present analysis particular attention has been given to the age distribution and the geographical behavior of poliomyelitis in Massachusetts since 1907. This discussion is limited to a con-

sideration of the age distribution. The material on the geographical aspects will be published elsewhere. In the earlier study of Forsbeck and Luther,<sup>1</sup> it was noted that the percentage age distribution of the reported cases of poliomyelitis had been undergoing considerable variation. This change,

first noted about 1918, was still active in 1930. The same gradual alteration had been noted in other states by various authors.<sup>2</sup> To our knowledge, no satisfactory explanation of this phenomenon has yet been presented.

The age distribution of poliomyelitis in Massachusetts for the period during which records are available (1910-1947) is given in Table 1. The figures for the years 1907, 1911 and 1917 are

tolerance to rapid intravenous infusions of the solution of amino acids indicate that the present solution is better tolerated in man than those previously employed in this clinic. On several occasions the present product was satisfactorily employed, even though infused more rapidly, in persons in whom other hydrolysates had been discontinued because of nausea, vomiting or venous thrombosis. Over 70 per cent of the infusions were given at rates of administration more rapid than is usually possible with the available commercial hydrolysates. Because of the length of time previously required to infuse 50 to 100 gm of amino acids and the frequency of nausea and vomiting, parenteral protein therapy has unfortunately been limited, because of both inconvenience and discomfort to the patient and the constant vigilance required by the physician. Since these disadvantages are minimized by the present product, parenteral protein hydrolysate therapy is more practical, and the physician may, if necessary, provide optimum protein feeding entirely by the intravenous route.

When employed as a parenteral protein supplement, the available protein hydrolysates may greatly diminish the voluntary oral food consumption, their apparent benefits being thus negated.<sup>13</sup> The present solution of amino acids appears to have marked superiority in this respect. Because of the rapidity of infusion attainable as well as the short duration of the anorexia that may ensue, the proper spacing of the injection between feedings allows for normal food consumption at regular mealtimes.

Although mixtures of synthetic amino acids are extremely well tolerated in man at rapid rates of infusion,<sup>10, 14</sup> have no significant effect on the oral food consumption<sup>13</sup> and can maintain nitrogen balance,<sup>10, 14</sup> their practical use is greatly limited because of both their excessive cost and the inefficiency due to the nonnutritive value and urinary loss of many of the unnatural amino acid isomers that they contain. Their value has been mainly as an investigative tool from which knowledge concerning the amino acids required by man, the tolerance of individual and mixtures of amino acids, the loss of these substances in the urine and the utilization of the unnatural isomer of the amino acids has been obtained.

An ideal product is not yet available. Although the dicarboxylic amino acids (glutamic and aspartic) contribute to the production of nausea and vomiting,<sup>15, 16</sup> their virtual removal from this product has not entirely eliminated these undesirable responses. The greater incidence of nausea when larger quantities of amino acids are infused (even at slower rates of infusion) suggests that a "saturation point" may be reached. Infusions of 50 gm of amino acids twice daily (instead of a single 100-gm infusion) might be ex-

pected to diminish reactions. As mentioned above, many cases of nausea appeared to be due to a lowered individual tolerance.

The relative freedom from venous thrombosis with the enzymatic casein hydrolysate previously employed ("amigen") is comparable to that of the present product, whereas most other hydrolysates caused a much higher incidence.

The solution of amino acids was well tolerated by the patients with the various illnesses reported in this paper, including those with severe acute cirrhosis of the liver, and infants with infectious diarrhea of the newborn.

## SUMMARY

A 10 per cent solution of amino acids prepared by the complete acid hydrolysis of casein, devoid of peptides, largely freed of glutamic and aspartic acids and supplemented with dl-tryptophane and glycine, was administered 342 times to 62 subjects.

Over 70 per cent of all infusions were administered at rates usually unattainable with the previously available protein hydrolysates (50 gm of amino acids in 70-kg subject in less than an hour). All injections supplied at least 0.5 gm of protein per kilogram of body weight, and many were larger.

The clinical tolerance of the solution of amino acids was evaluated in normal subjects as well as in patients with a variety of illnesses requiring parenteral protein therapy. There was no apparent difference in the clinical tolerance of the amino acid solution whether it was given with glucose, saline, lactate or vitamins, or when it was given repeatedly.

The incidence of pyrogenic reactions was 0.3 per cent, nausea 9.4 per cent, vomiting 2.6 per cent, venous thrombosis 2.3 per cent, and transient anorexia 9.1 per cent.

Because of the rapid rates of infusion attainable with but few untoward reactions, it is concluded that the solution of amino acids employed in this study was better tolerated in man than the protein hydrolysates previously used in this clinic.

17 per cent of the cases of poliomyelitis reported during that year were nonparalytic. Data for certain other years also indicate that in general, nonparalytic cases constituted less than 10 per cent of the total number reported through 1917 and less than 50 per cent until 1920.

Reporting of nonparalytic cases became routine in 1935. During the succeeding eleven years nonparalytic cases have been recorded at an average rate of 37.0 per cent of the total for any one year. Partially complete data for 1931 show that 35.0 per cent of the cases were nonparalytic. There has been no apparent tendency for nonparalytic poliomyelitis either to increase or to decrease during the past decade. There is evidence, therefore, of an increase in the reporting of nonparalytic poliomyelitis from about 10 per cent to approximately 33.3 per cent of the total number of cases.

Since the rate of reporting of nonparalytic cases has been relatively steady since 1935, this increase in reported cases of nonparalytic poliomyelitis occurred in the period between 1918 and 1931. The significant factors responsible were greater knowledge of the disease as a result of the studies made during the great New York epidemic of 1916 and the introduction of convalescent serum for the treatment of paralytic cases. The reporting of nonparalytic cases was also stimulated to a great extent by the difficulties encountered in differentiating paralytic from nonparalytic cases. Apparently, once the habit of reporting such cases had been established, it continued to the present.

#### AGE DISTRIBUTION OF PARALYTIC AND NON-PARALYTIC POLIOMYELITIS

Although paralytic and nonparalytic poliomyelitis in Massachusetts are alike so far as the seasonal, geographic and sex distribution is concerned, the

TABLE 3 Percentage Age Distribution of Nonparalytic Poliomyelitis in Massachusetts (1935-1945)

AGE	NO OF CASES	PERCENTAGE
0-4	221	18.2
5-9	489	40.3
10-14	702	56.9
15-19	110	9.1
20	9	0.6
Total	1,215	

age distribution of the two varieties is dissimilar. The greatest number of nonparalytic cases occurs in the patients five to nine years of age, the second greatest in those ten to fifteen years of age, and the least in those under four years of age, the latter being the group in which the greatest number of paralytic cases are found. Difficulties in diagnosing nonparalytic poliomyelitis in infants and very young children may be the most significant factor

in this observed difference. The age distribution of the nonparalytic cases has remained relatively unchanged since 1935 (Table 3). Although the data concerning nonparalytic cases in the years prior to 1935 are less complete, there is no evidence from

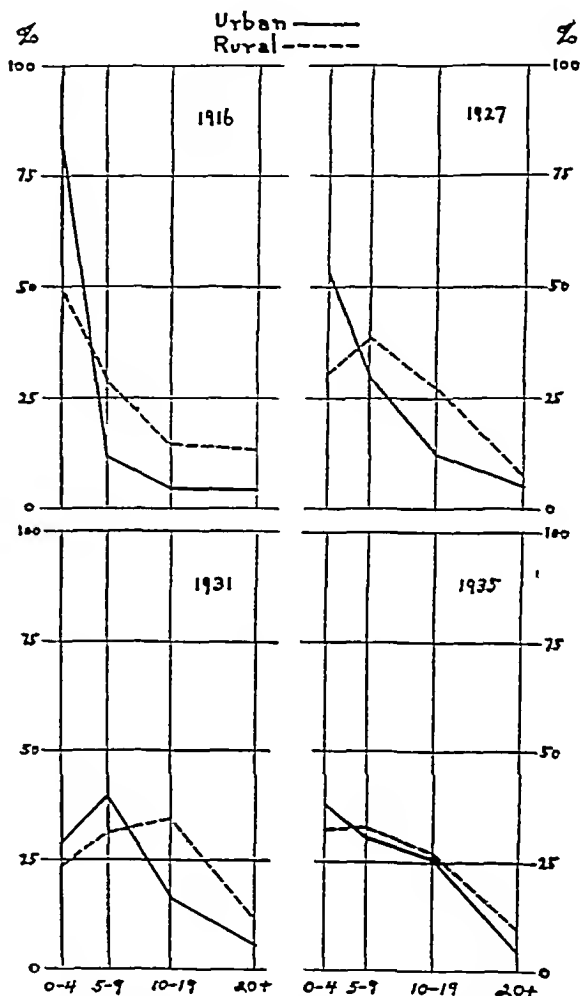

FIGURE 2. Urban (Cities with Populations of More Than 100,000) and Rural (Towns with Populations of Less Than 2500) Age Distribution of Poliomyelitis in Massachusetts for Epidemic Years

the available information that the age distribution of this disease has been different for these periods.

Since the age distribution of the nonparalytic cases, as noted above, differs from that of the paralytic, it would be expected that the addition of a gradually increasing proportion of nonparalytic cases would alter considerably the age distribution of the total. The more marked changes would be a decrease in number of nonparalytic cases in the patients under four years of age and increases in those five to nine and ten to fourteen years of age. The change would be most striking between 1927

lacking, and those for 1910 to 1916 are not available in all age groups

These data, presented graphically in Figure 1, differ from those used by Forsbeck and Luther<sup>1</sup> in that the figures for the various age groups are here shown as five-year moving medians. By this method trends become more apparent. It is noted that the decrease in the group of patients under four years of age from 1918 to 1920 seems somewhat exaggerated when compared with the actual percentages as given in Table 1.

The missing values for the years 1911 and 1917 have been obtained by interpolating a figure mid-

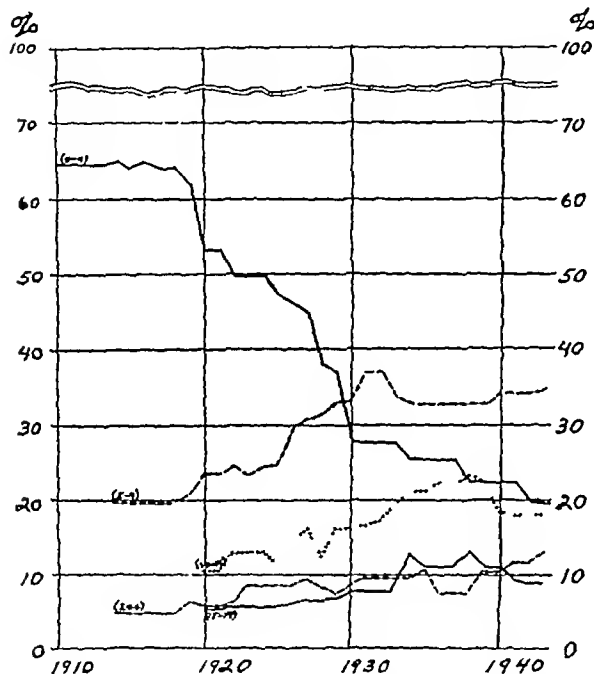

FIGURE 1 Age Distribution of Poliomyelitis in Massachusetts, 1910-1943 (Five-Year Moving Medians)

way between the middle values of the two years immediately preceding and following the year for which the value is lacking. The figures so obtained have been inserted in parentheses in Table 1.

Although the data are incomplete in the first decade (1910-1920), it is apparent that the age distribution during this period remained relatively constant. In the last two years of this period — namely, 1918 and 1919 — a decline occurred in the patients under four years of age, with a compensatory increase in the group from five to nine years of age. During the next decade (1920-1930) a continuation of this trend is noted, with the greatest decrease between 1927 and 1930 in the patients under four years of age. The compensating increases are most striking during this decade in the patients from five to nine and those from ten to fourteen years of age, with small increases in the

two remaining categories. From 1930 to 1943 the decrease in the patients under four years of age is still apparent, although less marked, and the increases in other age groups are much less spectacular.

#### CHANGES IN AGE OF THE POPULATION

In 1900, 1910 and 1920 persons under four years of age constituted respectively 10.1, 9.8 and 10.0 per cent of the total population in Massachusetts. This period of stability in the population corresponds with a period in which the age distribution of poliomyelitis remained stationary. In 1930 the same age group comprised 8.2 per cent of the entire population of the Commonwealth, and in 1940 it decreased by about a third — to 6.5 per cent. The decrease in the incidence of poliomyelitis in this age group, however, for the same period was over two thirds and therefore cannot be explained totally on the basis of aging population. The change in

TABLE 2 Ratios of Rates under Five Years of Age to Total Rates for Paralytic and All Cases

YEAR	ALL PATIENTS			PARALYZED PATIENTS		
	UNDER 5	ALL AGES	RATIO	UNDER 5	ALL AGES	RATIO
1910	147.47	25.10	5.87	147.47	25.10	5.87
1920	96.00	18.07	5.31	96.00	18.07	5.31
1935	141.90	32.24	4.39	101.90	19.37	5.27
1940	5.19	1.04	3.05	2.13	0.59	3.61

population age distribution has undoubtedly been a significant factor, but that it is not the only factor is apparent from Table 2, from which the influence of the variation in annual incidence of poliomyelitis and the aging population has been removed by the use of a ratio between specific and total morbidity rates. From this table it is apparent that the ratio is lower for the more recent years (1935-1940) and this would not have occurred had the change in age distribution of the population been the only factor concerned.

During the period between 1930 and 1940 it was found as previously noted that the decrease in the incidence of poliomyelitis among children under four years of age was much less than that in the previous decades. The reduction is, however, proportionate to the decrease in that age group of the population during the same period and may therefore be considered as having been caused by it. However, the marked change that occurred between 1920 and 1930 must have been caused by some factor or factors in addition to that of alteration in age of the population. This factor would have to be one that was most marked between 1918 and 1930, particularly between 1927 and 1930, and one that remained active after 1930.

#### REPORTING OF NONPARALYTIC POLIOMYELITIS

The annual report of the Massachusetts Department of Public Health for 1909<sup>2</sup> states that

## SPLENIC RUPTURE IN INFECTIOUS MONONUCLEOSIS\*

JOSEPH J TIMMES, M.D.,† JAMES H AVERILL, M.D.,‡ AND JAMES METCALFE, M.D.§

NEWPORT, RHODE ISLAND

**R**UPTURE of the spleen in infectious mononucleosis is a rare complication of a rather common disease. King,<sup>1</sup> in 1941, presented the first authenticated case. Since then 13 additional cases have been reported.<sup>2-8</sup>

It is the purpose of this paper to present 2 additional cases of infectious mononucleosis complicated by splenic rupture. In 1 of these the primary pathologic process was unsuspected preoperatively. In the other the diagnosis had been established before operation was undertaken. Subsequent to splenectomy both patients recovered full health, and microscopical changes consistent with those described as occurring in infectious mononucleosis were found in both the removed spleens. In one of these cases rupture apparently followed slight trauma to the abdomen. In the other, spontaneous rupture appears to have occurred.

Previously reported cases include only two in which splenic rupture followed definite abdominal trauma.<sup>5,6</sup> It must therefore be emphasized that rupture of the spleen in infectious mononucleosis may occur spontaneously or as the result of such trauma as that involved in defecation or in palpation of the abdomen in the course of physical examination.

Smith and Custer<sup>6</sup> first called attention to the time element of pre-existing symptoms in relation to splenic rupture. Table 1 includes an estimate of this time factor in the reported cases. In only 1 case (reported below) did splenic rupture occur less than two weeks after the onset of symptoms. This tends to support the statement made by Smith and Custer<sup>6</sup> that not until the third week have the capsular and trabecular changes progressed sufficiently to permit rupture, either spontaneously or as the result of slight trauma.

Consideration of the data summarized in Table 1 leads to the impression that a preoperative diagnosis of infectious mononucleosis was made in only 7 of the 16 cases. It is interesting to note that in the 7 cases in which a diagnosis of infectious mononucleosis had been made there was only 1 subsequent death, in that case no operation was performed because the diagnosis of ruptured spleen was not made. In the 9 undiagnosed cases 3

patients died without benefit of operation, and 2 died postoperatively. The over-all mortality in the 16 cases was 30 per cent. Although this series is too small to draw statistical conclusions it seems reasonable to hope that with increasing awareness of the fact that spontaneous rupture of the spleen may occur in infectious mononucleosis, more prompt and decisive operation will result, with subsequent improvement of the survival rate in this dangerous complication of an otherwise benign disease.

## CASE REPORTS

Case 1. R. E. M., a 19-year-old seaman second class, entered the hospital on September 8, 1947, with the chief complaint of pain in the left upper abdomen of 48 hours' duration. One month before admission he had developed swollen cervical lymph nodes and fever associated with malaise and anorexia. He had no sore throat or infection about the head or neck at that time to account for the lymphadenopathy. He was treated with penicillin, and apparently his symptoms subsided in several days. On September 4, while roughhousing, he was struck a light blow in the epigastrium, which was not severe enough to knock him down. Upon arising on September 6 he noted mild left-upper-quadrant pain which suddenly became severe and doubled him up. This pain remained constant until entry, except for periods of increased severity when it radiated to his left shoulder. His symptoms were aggravated by coughing or deep breathing and relieved partially when he sat upright. On the day of admission feverishness and generalized abdominal pain were present. Nausea, vomiting, diarrhea and headache were denied.

Physical examination revealed a hot, flushed, somewhat dehydrated patient, there was a questionable icteric tint to the sclerae. There was limitation of expansion of the left side of the chest because of the abdominal pain, but the lungs were clear. Examination of the heart was not remarkable. The abdomen was diffusely tender, but most tender in the left upper quadrant, where there was a sense of fullness and a questionable mass. Throughout the abdomen there was "a doughy type of rigidity."

The temperature was 100°F, the pulse 108, and the blood pressure 124/72.

Examination of the blood disclosed a red-cell count of 5,400,000, with a hemoglobin of 9.5 gm., and a white-cell count of 7200. A differential white-cell count was not done at that time.

The patient was taken directly to the operating room. A high, left-rectus-muscle-splitting incision was made under nitrous oxide, oxygen and ether endotracheal anesthesia. Blood clots and free old blood were found in the peritoneal cavity. An enlarged spleen was encountered with a large hematoma on its lateral surface. The spleen was not adherent, but in freeing the superior pole by blunt dissection, it was further ruptured into several fragments. The fragments were manually removed, and the pedicle ligated en masse. During manipulation of the spleen the patient went into profound circulatory collapse, which responded to the intravenous infusion of 1500 cc of whole blood. The abdominal wall was closed in layers without drainage.

The postoperative course was remarkably smooth, without any evidence of a pulmonary complication. He became ambulatory on the 3rd postoperative day.

On September 25 heterophil-antibody agglutination was positive in dilutions up to 1:1792, and a blood smear showed 63 per cent neutrophils, 34 per cent lymphocytes, 1 per cent

\*The opinions or assertions contained herein are the private ones of the authors and are not to be construed as official or reflecting the views of the Navy Department or the Naval Service at large.

§Member, Department of Medicine, United States Naval Hospital formerly medical house officer, Peter Bent Brigham Hospital.

and 1931, when the stimulus to increased reporting of nonparalytic cases was most dominant. This is precisely the pattern of the change in the age distribution of the disease from 1918 to 1930 that was not wholly explained by the variation in the population as mentioned above.

If the change in age of the population and increased reporting of nonparalytic cases were responsible for the major portion of the alteration in percentage age distribution, and if only paralyzed cases were considered, the relation between the morbidity rates for poliomyelitis in the whole population and in the group under five years of age should show no marked change during the period under observation. In Table 2 such a relation is presented for sample years. Census years have been used except for 1935. This table suggests a relatively constant ratio of approximately 5 cases in the patients under five years of age, to each 1 in the general population for the four sample years. It may therefore be concluded that there has been no essential change in the epidemiologic behavior of poliomyelitis in Massachusetts and that the apparent variation in its age distribution has been due almost entirely to two factors: a change in the age distribution of the population, and an increase in the reporting of nonparalytic cases.

#### URBAN-RURAL AGE DISTRIBUTION

Figure 2 represents the urban and rural percentage age distribution of poliomyelitis in Massachusetts for epidemic years. The age grouping ten to nineteen only is used because the data for 1916 are available only in this form. The distribution shows the same changes previously discussed — namely, a decrease in the patients under four years of age and increases in the older age groups. In addition, the marked difference between urban

and rural distributions that existed in 1916 has gradually decreased until in 1935, although still apparent, it is less striking. Similar differences between urban and rural age distributions are found in other communicable diseases, particularly the virus infections of childhood. It is generally accepted that these changes are due to the greater dispersion of the population in rural areas, resulting in relatively fewer cases at early ages and more among older persons. In Massachusetts there are comparatively few isolated communities at the present time, whereas in 1916 there was a larger number of truly rural areas. The great increase in automobile travel, the expansion of cities and changes in rural school systems have tended to increase the opportunities for exposure of rural populations to infectious diseases.

#### SUMMARY

Changes in the percentage age distribution of poliomyelitis in Massachusetts since 1907 are presented.

It is concluded that there has been no essential change in the epidemiologic behavior of the disease, and that the apparent change in its age distribution has been caused by an alteration in the age of the population and an increase in the reporting of nonparalytic cases.

The difference between urban and rural age distributions of poliomyelitis in Massachusetts is rapidly disappearing.

#### REFERENCES

1. Forsbeck, F. C. and Luther, E. H. Anterior poliomyelitis in Massachusetts, 1907-1929. *New Eng. J. Med.* 203: 1115-1121, 1930.
2. International Committee for the Study of Infantile Paralysis. *Poliomyelitis*. 562 pp. Baltimore: Williams & Wilkins, 1923. P. 383.
3. Massachusetts Department of Public Health. *Annual Report* 1930.

Physical examination revealed an acutely ill, toxic, dehydrated and hyperpeptic patient. Bilateral enlargement of the axillary lymph nodes was noted, and a few coarse rhonchi were heard throughout both lung fields.

The temperature was 104°F, the pulse 112, and the respirations 26. The blood pressure was 125/80.

A plain film of the abdomen revealed gaseous distention of the small bowel and a large left-upper-quadrant mass (Fig 1).

Examination of the blood disclosed a red-cell count of 4,100,000, with a hemoglobin of 12.5 gm., and a white-cell count of 9600, with 13 per cent neutrophils, 64 per cent lymphocytes and 3 per cent monocytes. Many of the lymphocytes were large and immature, and were very suggestive of infectious mononucleosis. A blood Kahn test was negative. Initially, examination of the urine showed the presence of acetone bodies, which subsequently cleared with rehydration.

A Miller-Abbott tube was passed. The patient was started on penicillin therapy, 100,000 units every 3 hours, and given intravenous fluids.

On December 15 a heterophil-antibody agglutination was positive in dilutions up to 1:3584. With persistence of abdominal findings and the probability of infectious mononucleosis, a tentative diagnosis of a subcapsular splenic hemorrhage was made.

Under nitrous oxide, oxygen and ether endotracheal anesthesia a left subcostal incision was made, with transverse sectioning of the left rectus muscle. When the peritoneal cavity was entered blood clots and free, dark blood were encountered, estimated at 500 cc. in amount. The spleen was enlarged and exhibited a ragged laceration of the capsule measuring 4 by 6 cm. on the anterior surface of the lower pole and a few small lacerations of the capsule over the lateral surface. The splenic pulp lay exposed through the capsular rents, did not appear ruptured and was not bleeding. As the spleen was not adherent it was easily separated by blunt dissection from its diaphragmatic and renal attachments and manipulated to a position outside the abdomen. Segmental ligation of the pedicle was carried out, and after all free blood had been aspirated from the peritoneal cavity the abdominal wall was closed in layers.

The postoperative course was essentially uneventful. The feared atelectasis, pneumonia and pleural effusion frequently seen after splenectomy were avoided, it is believed, by frequent inspiratory exercises, turning maneuvers, carbon dioxide inhalations and the prophylactic use of penicillin.

The gross specimen consisted of a spleen weighing 250 gm. when fixed. It was markedly abnormal, containing a large amount of clotted blood beneath the capsule, and appeared more friable than normal when handled. On microscopical examination the sections were those of a spleen with slight to moderate distortion of the architecture. The capsule was of average thickness throughout. The parenchyma was made up for the most part of large mononuclear endothelial-type cells, with round to oval vesicular nuclei. They were indistinguishable from the large, swollen endothelial cells lining the sinusoids. The malpighian corpuscles were moderately obliterated, with no distinguishable central arterioles. There were many subcapsular dilated sinusoids filled with red cells and atypical mononuclear leukocytes.

The pathological diagnoses were acute splenitis and infectious mononucleosis.

## Discussion

Rupture of the spleen in infectious mononucleosis, although rare, does occur. Furthermore, its apparent rarity may be due in some part to lack of awareness of the syndrome among those who are called upon for emergency removal of the ruptured spleens. With more general appreciation of the fact that in infectious mononucleosis splenic rupture may occur either spontaneously or as the result of minimal abdominal trauma three things may be accomplished. The performance of diagnostic tests for infectious mononucleosis in patients suspected of splenic rupture, and in the postoperative

study of those from whom a ruptured spleen has been removed, may lead to a revision of the present estimate of the rarity of the condition discussed. Secondly, such simple prophylactic measures as avoidance of heavy exertion during the phase of infectious mononucleosis in which the spleen is enlarged and avoidance of repeated palpation of an enlarged spleen in patients with infectious mononucleosis, as emphasized by Smith and Custer,<sup>6</sup> may lower the incidence of this complication (this consideration assumes increased importance when it is realized that although infectious mononucleosis is a benign disease splenic rupture carries a high mortality). Finally, careful observation of patients with infectious mononucleosis for evidence of abdominal pain or acute blood loss may lead to more prompt and definitive surgical action, with resultant improvement in the mortality figures of this complication. Awareness of the syndrome certainly played an important role in the decision to operate on the second case reported above when the diagnosis of infectious mononucleosis had been established.

In neither of the cases reported did the total white-cell count rise above 10,000 after splenic rupture. This is at variance with the usual findings in splenic rupture and with the majority of the reported cases of the syndrome under discussion.

Smith and Custer<sup>6</sup> were the first to state that rupture of the spleen seldom occurs prior to the third week in the course of infectious mononucleosis. A review of the literature appears to support this statement.

## SUMMARY

Fourteen cases of splenic rupture in infectious mononucleosis reported in the literature are reviewed, and 2 additional cases are presented.

Careful consideration of the reported cases suggests that awareness of the syndrome leads to more decisive action, with a consequent decrease in mortality.

Since splenic rupture occurs in infectious mononucleosis after minimal trauma, repeated abdominal palpation and strenuous exertion while the spleen is enlarged are contraindicated.

ruptured, and the surface was covered with clotted blood. The cut surface revealed many areas of hemorrhage and clotted blood within the spleen itself. These areas varied from pin-point size up to several centimeters in diameter. The splenic pulp appeared homogeneous and grayish. On microscopical examination, performed at the United States Naval Medical School, section of the spleen showed several areas of extensive hemorrhage, with disruption of the tissue in these areas. Elsewhere the splenic structure demonstrated a normal number of malpighian bodies. In many of them the germinal cells were enlarged and disclosed rather marked reticuloendothelial hyperplasia. Throughout, the red pulp and sinusoids were somewhat dilated, and the reticuloendothelial cells lining the sinusoids had markedly enlarged, somewhat irregular, oval to round nuclei, which were very vesicular. There was rather marked hyperplasia of these cells throughout the tissue. Many polymorphonuclear leukocytes were found scattered throughout the tissue. Many of the sinusoids contained rather bizarre atypical cells. The cellular detail was rather distorted, and a definitive diagnosis of infectious mononucleosis could not be made. However, the histologic appearance was compatible with such a diagnosis.

The pathological diagnosis was probable infectious mononucleosis, with rupture of the spleen.\*

The diagnosis in this case was not suspected preoperatively. However, the history of lymphadenopathy, the strongly positive heterophil-antibody agglutination and the splenic disease made the diagnosis extremely probable.<sup>9</sup>

Case 2 C K, a 19-year-old seaman first class, was admitted to the hospital on December 14, 1947, complaining of nausea and vomiting of 4 days' duration and abdominal pain of 24 hours' duration. The patient had been perfectly well until 1 week before admission, when he developed a "cold" characterized by coryza, a moderately severe sore throat, slight cough and malaise. He had no headache and did not feel sick enough to report to his doctor. Four days before admission he became nauseated and began vomiting. In the course of the next 4 days he vomited frequently and took only fluids by mouth. His bowel movements were normal. On the day prior to admission, while retching, he suddenly developed a severe, sharp pain in the left upper quadrant, which radiated to the left shoulder, and he reported to the sick bay. Shortly thereafter the pain became generalized. Physical examination at that time revealed a pale young man in moderately acute distress. The temperature was 99.4°F,

active. The patient was given intravenous fluids, Was genstein suction and was placed under observation. On the following day extreme tenderness below the left costal

FIGURE 1 Plain Film of the Abdomen in Case 2, Showing the Large Mass in the Left Upper Quadrant

margin and rebound tenderness in the hypochondrium were present, a questionable mass in the left upper quadrant was felt, and he was transferred to the hospital.)

tion must be considered as one of the important regions where a special circulation significantly conditions general hemodynamics

Comparing hepatic blood flows as estimated above in normal nonpregnant women with those in normal pregnant women at various stages of gestation, and with blood flows in pregnant women with toxemia, Munnell and Taylor<sup>118</sup> found that pregnancy was without influence on hepatic circulation. In 6 toxemic women one exceedingly high rate of 4070 cc per millimeter was found — almost exactly twice the highest value found in the normal pregnant group. Whereas no more than suggestive of a change in liver circulation in toxemia of pregnancy, the finding deserves further elucidation.

Another method of assessment of liver circulation has been devised by Lipscomb and Crandall.<sup>119</sup> Urea excretion is measured by urine collection, and this quantity divided by the portal-hepatic venous difference in urea, assuming that urea is produced in the liver and quantitatively excreted by the kidneys. Despite certain inherent difficulties that magnify the error in analysis of urea concentration (the portal-hepatic urea difference is small, averaging close to 10 mg per 100 cc) the procedure was found to check reasonably well with the bromsulphalein method. Myers<sup>120</sup> estimated hepatic flow by the urea method in 10 subjects and obtained an average of 1.0 liter per square meter of body surface per minute. With the bromsulphalein method he produced an average flow of 0.8 liter per square millimeter per minute, comparing well with Bradley's value of 0.9 liter.

#### *Other Special Circulations*

Catheterization of the renal vein has permitted studies of the extraction of oxygen and sodium para-amino hippurate by the kidneys for validation of other methods<sup>121</sup> and makes possible the assessment of the influence of intra-abdominal and venous pressure upon kidney function.<sup>122</sup> Studying the renin content of blood obtained by catheterization from the renal vein of 12 hypertensive patients and in comparable samples from 12 normal subjects, Haynes, Dexter and Seibel<sup>123</sup> found small but detectable amounts of renin in 7 of the 12 in each group. Superficially considered at least, this finding does not support the hypothesis that renin is the hormone responsible for human hypertension.<sup>123</sup> The observation that the Cournand catheter sometimes passes into the coronary venous sinus, as shown by its radiologic position and by the low oxygen content found in blood samples obtained when it is in that position, has encouraged attempts to measure the coronary blood flow in man.<sup>124, 125</sup> These have been based on Kety and Schmidt's<sup>126</sup> method for measurement of cerebral blood flow. When low concentrations of nitrous oxide are rebreathed for a few minutes and serial samples of arterial blood and internal jugular blood are

obtained, a rising curve of the concentration of nitrous oxide in the arterial blood flow is inscribed, leveling off as equilibrium is reached. The curve of internal jugular blood concentration reaches the same maximum but at a later time and along a less steep curve, because of the loss of nitrous oxide to the brain by simple solution therein. If the nitrous oxide tension at the point of equilibrium is known, the total amount of the gas dissolved in a given weight of brain can be calculated from previously determined solubility curves. The arteriovenous nitrous oxide difference can be calculated from the area of the difference between the two curves of arterial and venous concentrations or by means of acceptable simplifications. Again the basic Fick calculation gives the cerebral blood flow in terms of unit volume of brain tissue. Measurement in monkeys checks reasonably well with determination by direct flowmeters.<sup>127</sup> Once the blood flow has been determined, it becomes possible to reverse the usual Fick calculation, and from this value and from direct determinations of arterial and internal jugular blood oxygen levels, to calculate the oxygen consumption of the brain.<sup>128</sup>

#### *The Lungs*

In the calculation of pulmonary blood flow by Vandam, Bing and Gray<sup>129</sup> it is assumed that blood returns from the lungs almost fully saturated (95 per cent). At operation these authors have had several opportunities to obtain pulmonary venous blood samples that proved as fully saturated as was expected, and Dr Arnold Johnson, at the Children's Memorial Hospital, Montreal, has passed a catheter through an interventricular septal defect into the left auricle and there obtained arterialized blood 95 per cent saturated with oxygen. By inserting the catheter far enough into a branch of the pulmonary artery to obstruct it, Dexter and his co-workers<sup>94</sup> withdrew blood that was 95 to 100 per cent saturated with oxygen. They drew the logical conclusion that pulmonary capillary blood had been drawn backward into the catheter.<sup>94</sup> This is not the opinion of Taussig and Blalock,<sup>129</sup> however, who conclude as follows:

We do not mean to imply that the lack of circulation to the lungs is the sole cause for the production of cyanosis and polycythemia, or that in the presence of polycythemia all of the blood which passes through the lungs is in effective contact with the oxygen in the alveolae (*sic*). On the contrary, the change in the patient's color when he is anesthetized and is receiving high concentrations of oxygen, offers clear evidence that without any fundamental alteration in the course of the circulation the oxygen saturation of the arterial blood may be greatly increased. In an attempt to analyze these factors, samples of arterial blood have been obtained prior to operation but after the patient was anesthetized and was receiving oxygen in high concentration. These samples have shown a striking increase in the oxygen saturation due to an increase in the oxygen content of the arterial blood, but, as is to be expected, there was no change in the oxygen capacity. These samples are truly basal, a condition which it is virtually impossible to obtain during an arterial puncture made when a child is

## SPECIAL CIRCULATIONS

*The Liver*

The unusual nature of the hepatic circulation has been emphasized by recently acquired evidence<sup>103</sup> that the oxygen supply to the liver may constitute the dominant factor determining whether shock becomes irreversible. It has been stated that the liver depends in large measure on portal blood for its oxygen,<sup>104</sup> and that increasing the oxygen content of portal blood by transfusion of arterial blood into the portal circulation protects the recipient against death from shock.<sup>105</sup> This view is in keeping with the classic anatomic opinion that the portal circulation is the major source of blood for the liver sinusoids. There can be no doubt, however, on anatomic grounds alone, that the hepatic artery also supplies the sinusoids, through anastomoses via the bile capillaries, direct arteriportal venous anastomoses and intralobular anastomoses.<sup>106-109</sup> Pathologically, the variable results of occlusion of portal or arterial vessels suggest that the relative contribution of the two vessels indeed varies. Grindlay, Herrick and Mann<sup>110</sup> measured portal inflow and hepatic venous outflow by the thermostromuhr method and found total flows averaging 100 cc per 100 gm of liver per minute, the hepatic artery flows constituting from 10 to 30 per cent of the total flow in the nonanesthetized animal. In anesthetized animals it was significantly higher, at times even exceeding the contribution of the portal vein.

This concept of dynamic variability of the portal circulation has much other evidence to support it. Rein and his co-workers<sup>111</sup> obtained flows of 62 to 75 cc per 100 gm per minute by the thermostromuhr method, with much the same partition between arterial and portal venous contributions. They also noted that, when adrenalin was given, more blood left the liver than entered it, so that the liver discharged as much as 60 per cent of its weight in blood. Bauer et al.<sup>112</sup> confirmed this finding in perfused livers and concluded that in the dog liver outflow is controlled by a variable sluice mechanism at the hepatic venous side of the circulation that could be closed by histamine or opened

by epinephrine or sympathetic-nerve stimulation. In much the same kind of study McMichael<sup>113</sup> found that a portal venous hypertension followed administration of epinephrine, presumably by vasoconstriction in the ramifications of the portal system in the liver. Wakim<sup>109</sup> saw on microscopical examination of the liver in situ an intermittence in the activity of lobular sinusoids, which could remain relaxed and engorged with stagnant blood only to expel it later. All the foregoing evidence points strongly to a storage function in the operation of liver circulation.

Employing an ingenious adaptation of the Fick principle combined with catheterization of the hepatic vein in man, Bradley<sup>114-116</sup> has estimated the minute volume of the hepatic circulation. Assuming that the dye bromsulfalein is removed from the blood stream by the liver and no other organ, one can calculate liver blood flow by dividing the total quantity of the dye removed from the circulation in a given time by the difference in the concentration of the dye in systemic and hepatic blood. The total amount removed Bradley determined by the quantity of the dye injected in a given time when the rate of injection was balanced against the rate of removal in the liver to give a constant concentration in the blood. Values so calculated ranged from 1085 to 1845 cc per minute in the adult human subject, with an average figure close to 1500 cc per minute. Considering the average human liver to weigh 1500 gm, flows of 100 cc per 100 gm per minute were thus found, just as in the dog. After sympathectomy for hypertension in man, liver flow as measured in this manner rises markedly, provided blood pressure is maintained, indicating that in man as well as in animals the liver circulation is under sympathetic control.<sup>116</sup> Since cardiac output in man averages about 5.4 liters per minute in the basal state, it is apparent that hepatic circulation constitutes a significant proportion of the whole, equaling in fact the total renal blood flow. The two together make up very close to half the total cardiac output. Even if it is admitted that the liver is, by virtue of its portal supply, out of the main circulatory channel and thus unable to contribute greatly to the peripheral resistance by which systemic blood pressure is regulated and that its circulation must be subject to significant passive or secondary changes resulting from gastrointestinal circulatory regulation,<sup>117</sup> the liver circula-

blackwater fever, in which there is intravascular hemolysis, was noted. They also drew attention to the fact that the crush syndrome was not a new condition as they had previously thought but had been recognized by German clinicians and pathologists in World War I. A review of these cases was published by Minami<sup>135</sup> in 1923. De Navasquez<sup>136</sup> reported 3 fatal cases of transfusion reaction and pointed out that 2 of these patients had had alkaline urine, experimentally, when hemoglobin was injected into rabbits, animals with acid urine actually excreted more iron in their urine than those with alkaline urine. He also found insufficient tubular blockage to account for the anuria. Hence he concluded that mere hemoglobinuria was not the sole cause of anuria and that hemoglobin was not precipitated in undue amounts owing to the acidity of the urine, he suggested that diminished glomerular circulation might be the cause of the anuria. In 1942 Yuile<sup>137</sup> reviewed the literature on hemoglobinuria and concluded that hemoglobin was able to pass into the glomerular filtrate only after damage to the glomeruli, possibly because of anoxia. He also noted that not all cases of "transfusion kidney" at autopsy had pigment casts. Foy and his associates<sup>138</sup> suggested that the anuria in all hemoglobinurias, sulfonamide reactions, favism, crush injuries and so forth fell into a common category, pointing out the rather similar pathological findings and suggesting that the lesion was caused by dehydration with diminished blood volume and renal circulation, in their opinion the pigment casts were only an aggravating factor.

Meanwhile in 1942 Barnes and Trueta<sup>139</sup> had been investigating the effects on the circulation of the rabbit's hind leg produced by a rubber-covered wire tourniquet applied to the thigh for four and a half hours. They found that this produced a severe spasm of the vessels of the affected limb for periods up to seventy-two hours (well beyond the period of shock and hemoconcentration), as well as a spasm of the arteries of the opposite limb. This was demonstrated by arteriography, thorotrast being injected into the abdominal aorta. During the laparotomy to expose the aorta, it was noted that the kidneys were pale and blanched on their surfaces but the authors were unable to pursue this observation at that time. Trueta et al.<sup>140, 141</sup> returned to this investigation in 1945. The subjects of the experiment were rabbits, and a variety of experiments were carried out. Serial radiography using thorotrast as the radiopaque material, revealed, after release of the tourniquet on the left hind limb in the intact animal, that the calibers of the renal artery and the femoral artery of the left side were greatly reduced, whereas there was some dilatation of the superior mesenteric artery. At laparotomy they noticed that the renal cortex was pallid, although the renal vein was redder than normal, often containing bright-red central stream-

lines and showing pulsations almost like an artery, suggesting a rapid circulation through part of the kidney at the expense of the cortex. This was confirmed by study of cineradiographs, which showed that the circuit time of the radiopaque mass through the affected kidney might be half that of the normal and the size of the renal artery was reduced to a quarter its normal size. The cortex of the affected kidney was less opaque than the medulla during the phase of the renal circulation when one would expect the cortex to be more opaque, furthermore, in the left kidney at that time it was noticed that although the thorotrast appeared in the renal vein sooner than normal, it took a longer time for the renal artery to be completely emptied. These observations suggested some sort of circulatory by-pass through the medulla of the affected kidney. To study this more fully dyes and particulate matter were injected into the arterial side of the circulation during the period of cortical ischemia, these substances stained and filled the medulla completely and yet did not appear in the cortex or stain the surface as in the normal kidney. Histologic examination of the kidneys after injection of the India ink localized the pigment in the vasa recta of the medulla and in subcortical vessels of considerable size. These changes in the renal circulation could also be evoked by the intravenous injection of adrenalin, pitressin or staphylococcus toxin, with the injection of the last substance an extreme degree of cortical ischemia was produced, resulting in a pathologic lesion identical with that found in bilateral cortical necrosis. Similar but less extensive cortical ischemia was found in animals that had been bled sufficiently to produce shock. Stimulation of the central end of the divided left sciatic nerve or the distal end of the divided splanchnic nerves also caused renal cortical pallor and medullary circulatory by-pass. When, however, the splanchnic nerves were previously divided the renal circulation in the tourniquet of otherwise stimulated animals remained relatively unchanged, although the femoral artery of the affected limb and the mesenteric vessels showed some constriction.

From these experiments it was concluded that a similar mechanism producing cortical ischemia could be the cause of the azotemia and oliguria seen in renal injury due to sulfonamides and transfusion of incompatible blood, Weil's disease, cholera, crush syndrome, hysterical anuria and so forth. In support of this theory a considerable body of experimental, clinical and pathological evidence has been presented in recent years. In 1944 Richards<sup>142</sup> found in studies of the circulation in traumatic shock in man that when cardiac output dropped to about half normal renal blood flow fell to a tenth or twentieth of normal, and simultaneously that the urine output fell, he saw renal failure only once in these cases, however. Selkurt<sup>143</sup> cannulated the renal vein via the jugular to avoid local trauma and

conscious. These values are probably influenced both by inhalation of a high concentration of oxygen and by the basal condition associated with anesthesia, and possibly by the anesthetic agent. The relative importance of these factors is not easy to determine. Nevertheless, the fact that there is a rise in the oxygen saturation of the arterial blood when the patient is given a high concentration of oxygen is in accord with the existence of pulmonary factors emphasized by Lundsgaard and Van Slyke in their classical studies on cyanosis.

Such a difference of opinion emphasizes how limited knowledge of the precise details of the pulmonary circulation, especially in man, has been, and shows how the new technics will prove of value, both by raising problems and by providing their solution.

The technic of catheterization has been combined with pressure recording by means of the Hamilton or other manometers, to make possible, for the first time in man, a direct quantitative study of the pressure relations of the pulmonary circulation.<sup>120</sup> In 77 catheterizations in 70 subjects, mean right arterial pressures varying between  $-2$  to  $+2$  mm of mercury were found in recumbent normal subjects. Pulse pressures ranged from 4 to 8 mm of mercury. Curves showed peaks of pressure associated with auricular systole, closure of the auriculoventricular valves and accumulation of blood in the auricle during ventricular systole. The second peak is followed by an abrupt fall in pressure with descent of the ventricular base, after the third peak of pressure there is a rapid fall as interventricular pressure falls, and the phase of early diastolic filling of the ventricle begins. In the right ventricle maximum systolic pressures in normal subjects range between 18 and 30 mm of mercury, averaging 25 mm. Among patients with lung disease, increased systolic pressures were found in the right ventricle in 14 out of 19 patients with chronic pulmonary fibrosis in the absence of failure of the right side of the heart and without elevation of diastolic pressures in the right auricle or ventricle. Patients after pneumonectomy or pneumothorax had normal pressures. A marked elevation in right ventricular pressure was found in a single patient with mitral-valve disease without evidence of right ventricular failure.

In the presence, however, of venous congestion coincident with right ventricular failure, diastolic pressures in the auricle and ventricle rose (7 to 9 mm of mercury in 1 case), diminishing markedly the normal gradient of pressure between the peripheral veins and the right auricle. The intraventricular pressure curves showed characteristic alterations in contour, one of the most constant being an accentuation of the early diastolic "dip" in the ventricular and auricular pressure curves due to the sudden relaxation of the ventricle.

These findings have significance when considered from the standpoint of pulmonary cardiodynamics since the outputs of the right and left ventricles are equal over long periods, the pulmonary circu-

lation in general equals the systemic, which means in turn that pulmonary resistance must be very low indeed to permit such a large flow at such low pulmonary pressure, whereas under most circumstances there is equal output from the two ventricles, the capacity and flexibility of the small vessels of the lungs are such that considerable variations in the quantity of blood in the lungs can occur, so that during accumulation or discharge of this stored blood, right ventricular output may temporarily exceed or be less than left ventricular output. Quite the reverse, alterations of right or left ventricular output can influence the quantity of blood in circuit through the lungs.<sup>121</sup>

Whether the lung vessels have a clear-cut vasomotor regulation was still left in doubt by these studies, but Cournand et al.<sup>122</sup> have recently found evidence of another type of some kind of active regulation of peripheral resistance in the lungs. When normal adult males breathed mixtures of 10 per cent oxygen in nitrogen instead of room air, mean pulmonary artery pressure rose from 13 to 23 mm of mercury, diastolic from 6 to 13, and systolic from 22 to 35. Calculated pulmonary resistance doubled. The maximum increase in pressure was reached within two to four minutes, the elevation of pressure remained as long as the subject breathed the low oxygen mixture, and fell rapidly back to normal as room air was readmitted to the subject. Cardiac output fell as much as 20 per cent. Animal experiments by other workers suggest that the phenomenon is an expression of a direct sensitivity of the pulmonary arterioles to oxygen lack, which serves to direct blood from nonaerated portions into regions of better oxygenation, where arterioles are in consequence relaxed.

#### RENAL DISEASE IN THE LIGHT OF RECENT STUDIES ON THE RENAL CIRCULATION

With the report by Bywaters and Beall,<sup>123</sup> in 1941, of 4 cases of azotemia, oliguria and finally fatal anuria following crushing injury to the extremities sustained in the bombing of London, numerous workers began to investigate the clinical and pathological features of many different conditions that give rise to renal shutdown. Bywaters and Dible<sup>124</sup> described the typical pathological features of crush syndrome in which there is pallor of the renal cortex and degeneration of the convoluted tubules, which are often filled with desquamated debris and pigment-containing casts, the pigment was identified as myoglobin, a substance related to hemoglobin and presumably liberated by the crushing injury to large amounts of muscle. They speculated on the part played by the pigment casts in the production of oliguria by mechanical obstruction or by toxic effect on the kidney, and came to the conclusion that it was probably an aggravating factor but not necessarily the entire cause, the similarity of this lesion to that seen in

rendered ischemic by some hours of binding with a tourniquet, which depressed creatinine clearance in the kidney, it was also observed in muscles of dead animals between four and ten hours post mortem, after which time it disappeared. This substance was unstable and could not be dialyzed. If injected slowly through the portal vein it produced no effect suggesting that it was detoxified by the liver. Lucké<sup>152</sup> postulated that this explained the occurrence of hepatorenal syndrome after operation on the biliary tract when there is presumed to be some alteration of liver function. That nervous inhibition of urine function can occur is shown by the experiments of O'Connor and Verney<sup>158, 159</sup> in 1942 in which they demonstrated two types of emotional inhibition of water diuresis in dogs produced by sounding a horn or faradic stimulation of the skin, one being rapid and the other slow and delayed. The rapid type is abolished by sympathectomy, and the authors suggest it is due to renal ischemia produced by impulses traveling in the splanchnic nerves, the second is due to the antidiuretic hormone of the pituitary body. Similarly, Charcot<sup>160</sup> reported cases of hysterical anuria in 1877. On the other hand Smith,<sup>161</sup> using clearance studies of renal circulation, showed that increased sympathetic tone induced by elevating a previously supine man on a tilt table caused renal vasoconstriction primarily in the afferent arterioles, a similar effect was produced by psychomotor stimuli.

Having found that such a medullary by-pass existed Trueta and his co-workers<sup>141</sup> investigated the anatomy of the renal circulation by means of neoprene casts, some being made in rabbit's kidneys and others in those of human subjects. To show the side of this by-pass they injected the renal arteries of rabbits after producing cortical ischemia experimentally. At times this still did not enable them to demonstrate fully the flow into the vasa recta of the medulla, so that they first injected large quantities of thorotrast into the rabbit's arterial system, which they found completely blocked the cortical glomeruli. Using these techniques in the rabbit's kidneys and by straight injection techniques in human kidneys they found that the by-pass in circulation occurred through what Heggie<sup>162, 163</sup> called the juxtamedullary glomeruli. In these glomeruli the circulation of the nephron is somewhat different to that which occurs in the cortical glomeruli. In the latter, as originally described by Bowman<sup>164</sup> in 1842, the blood travels through the interlobular arteries and thence to the afferent arterioles and the capillaries of the glomerulus from which emerges the efferent arteriole, which then breaks up into the capillaries surrounding the convoluted tubules, and after following the descending and ascending limbs they reunite to join the venous side of the circulation. In the juxtamedullary glomeruli the following differences were noted. First of all it was found that the efferent

arteriole—unlike that in the cortical glomeruli—was larger than the afferent arteriole. Secondly, the efferent arteriole does not break up into the usual capillaries that surround the convoluted tubules, but immediately forms large vessels which descend into the medulla as the vasa recta. These vessels, the vasa recta, were always poorly described anatomically before this, since they were difficult to inject. Trueta et al<sup>141</sup> found that after descending for varying distances into the medulla they hook back upon themselves, forming curious "H" and "Y" forms, and that when they reach the juxtamedullary region they reunite to join the venous system. These vessels form very extensive thin-walled channels about the ascending and descending limbs of the tubules descending into the renal medulla. In this connection it was pointed out by Trueta et al<sup>141</sup> that Peter<sup>165</sup> showed in 1909 that the tubules of the cortical region only descended into the outer fringes of the medullary zone of the kidney, whereas those from the juxtamedullary-zone glomeruli were much larger, descending deeply into the medulla, and had a much longer loop of Henle. Hence these tubules are surrounded by the vasa recta through which the entire circulation of the kidney passes during the periods of cortical ischemia. Thus, there is further support for the theory that greater tubular reabsorption is a partial cause of traumatic anuria.

In their anatomic studies of the renal circulation in man Trueta et al<sup>141</sup> noted in many cases in these juxtamedullary glomeruli that there was marked degeneration of the glomerular capillaries, which at times was so extreme that there remained only a direct connecting channel, with a muscular coat, between the afferent and the efferent arteriole, the site of the degenerated glomerulus being marked only by a slight curve in the vessel. The vessels were only found in kidneys in which there was some degenerative process, and had been previously reported by MacCallum<sup>166</sup> in 1939. In all probability these vessels were what caused all the dispute between the earlier anatomists regarding whether or not Ludwig's arteriole, or the arteriae verae rectae, existed. They found no evidence of any other types of nonglomerular circulation.

Oliver<sup>167</sup> observed these degenerated glomeruli with a direct continuity between the afferent and efferent arteriole to be especially prevalent in cases of chronic Bright's disease. From this fact, and considering the role of renal ischemia in the experimental production of hypertension as shown by Goldblatt<sup>168</sup> and numerous subsequent workers, Trueta et al<sup>141</sup> suggest that there is some connection between this by-pass of normal renal circulation and the etiology of essential hypertension. They postulate that in normal persons, owing to varying stimuli, there is frequent re-routing of the renal circulation through the juxtamedullary glomeruli. When this mechanism is called into being too

spasm, and then made simultaneous recordings of renal clearance and blood flow during shock produced by hemorrhage. He found that when the pressure had fallen to 40 mm of mercury the renal circulation had dropped to 11 per cent of normal, but clearances of para-aminohippuric acid and creatinine were zero. However, when the blood pressure was raised by transfusion to about 80 mm of mercury and the renal blood flow was 80 per cent of normal, the clearance of para-aminohippuric acid and creatinine was not restored to normal but still remained nearly at zero. Selkurt could not explain this to his satisfaction, but it now seems that it was due to the re-routing of the renal circulation as described by Trueta et al.<sup>141</sup> Pathologically the kidneys of these dogs showed cloudy swelling and early degenerative changes in the tubular cells. Scarff and Keele<sup>144</sup> found in 1943 that clamping the renal artery in rabbits for an hour after the other kidney had been removed resulted in azotemia and oliguria, frequently going on to fatal uremia, and produced degeneration of the tubules, not unlike that found in crush syndrome and so forth, although it principally affected the proximal convoluted tubules rather than the lower part of the nephron. Corcoran and Page,<sup>145</sup> reviewing their experimental work on dogs in relation to post-traumatic anuria in 1936, reported that injection of hemoglobin or myoglobin into dogs and rats caused variable damage, which was frequently not serious even when the urine was acid, however, if this were accompanied by shock to produce renal ischemia, most of the animals died of anuria. From this they concluded that renal ischemia was the important factor in the pathogenesis of this condition. Lauson, Bradley and Cournand<sup>146</sup> found by studies of inulin and diodrast clearance in shocked men that there was a fall of renal blood flow out of all proportion to the fall of systemic blood pressure, which, they calculated from estimated renal artery and vein blood pressure and renal blood flow, was due to increased resistance in the kidney. Darmady et al.<sup>147</sup> and Darmady<sup>148</sup> analyzed a total of 17 cases of traumatic anuria occurring in the British forces in France in 1944-1945. All showed a clinical picture, developing about five or six days after injury, distinguished by azotemia, oliguria, elevated serum potassium and occasionally mild hypertension. Most of these patients had received blood transfusions at some time, but no reactions were recorded. In the 12 fatal cases the authors found the typical pathological features of degenerated convoluted tubules and frequent pigment casts in the tubules, whereas the cortices were pale and ghastening and the glomeruli rather avascular. They suggested that the lesion was due to renal anoxia, and noted that in 2 patients who recovered there was dramatic improvement after splanchnic block. Maegraith, Havard and Parsons<sup>149</sup> came to similar conclusions in 1945, after comparing the

pathological features of blackwater fever, incompatible transfusion, bilateral cortical necrosis, Weil's disease, hepatorenal syndrome, renal injury due to sulfonamides, crush injury and cholera. Duff and More<sup>150</sup> analyzed 71 cases of bilateral cortical necrosis of the kidney that came to autopsy, ascribing the pathogenesis to renal ischemia of unknown origin, which is possibly an individual idiosyncrasy to some stimulus or toxin. Mallory,<sup>151</sup> in 1947, and Lucké,<sup>152</sup> in 1946, after extensive analyses of over 500 cases of renal shutdown occurring in the American forces during the war, ascribed the renal lesion primarily to anoxia, although Mallory believed that the factor of mechanical blockage of the tubules could not be completely excluded and was certainly an aggravating factor.

Trueta et al.<sup>141</sup> ascribed the oliguria to reduced glomerular circulation and consequent low filtrate formation, and also to increased reabsorption in an unselective fashion from the tubules due to the increased blood flow in the vasa recta and the fact that the tubules are damaged. In support of the latter theory they cited the work of Dunn and Polson<sup>153</sup> in 1926 and Richards<sup>154</sup> in 1929, who found that in tubules damaged by uric acid or bichloride of mercury there is increased reabsorption of water with oliguria and with loss of normal impermeability to phenolsulfonephthalein. By this process Lucké<sup>152</sup> accounted for the presence of tubular casts, which he considered a result rather than a cause of oliguria, owing to excessive reabsorption of water. Brun, Knudsen and Raaschou<sup>155</sup> studied the effect of syncope on renal clearance of inulin and diodrast in man and noted that although renal plasma flow returned to normal within a few minutes, there was oliguria lasting for about sixty to ninety minutes. They concluded that this was due to increased tubular reabsorption and suggested that it was induced by the antidiuretic hormone of the posterior portion of the pituitary body, for blood withdrawn from these men during the period of oliguria produced oliguria in normal controls. There was also increased chloride excretion similar to that produced by the antidiuretic hormone, and in 2 men with diabetes insipidus the postsyncope oliguria was less marked than normal. Trueta and his co-workers<sup>141</sup> were undecided whether the cause of the ischemia was toxic or neurogenic, or both. Page<sup>156</sup> found a vasoconstrictor substance in blood during shock produced in dogs by trauma, hemorrhage or burns that caused vasoconstriction in the perfused vessels of a rabbit's ear, he decided that it was not histamine or angiotonin because when the vessels of the perfused ear were fatigued by repeated injections of this substance they still constricted with histamine or hypertensive plasma, and the converse was also found. This substance could be obtained in the blood after removal of the kidneys, adrenal glands and spinal cord. Eggleston<sup>157</sup> found a substance in muscles of dog's legs

# MASSACHUSETTS MEDICAL SOCIETY

## PROCEEDINGS OF THE ONE HUNDRED AND SIXTY-SEVENTH ANNIVERSARY

May 25, 26 and 27, 1948

THE one hundred and sixty-seventh anniversary of the Massachusetts Medical Society was observed at the Hotel Statler in Boston on May 25, 26 and 27, 1948

Seventeen hundred and forty-one physicians, 219 ladies and 495 exhibitors were registered

The Committee on Membership met in Parlor C at 4 30 p m on the afternoon of May 24 The Supervising Censors met in Parlor C at 5 00 p m This meeting was followed by the Cotting Supper in Parlors A and B, which was attended by 236 councilors The annual meeting of the Council was held in the Georgian Room at 7 00 p m with 235 councilors in attendance, as recorded in the attendance books

### TUESDAY, MAY 25

The first general session opened at 9 00 a m in the Georgian Room under the co-chairmanship of Dr Dwight O'Hara and Dr Frederick S Hopkins

The one hundred and sixty-seventh annual meeting of the Society was held in the Georgian Room at 11 00 a m, President Edward P Bagg presiding The attendance was about 400 Dr Bagg spoke on "The State of the Society," after which the annual oration, "The Responsibility of Medicine in the Propagation of Poor Protoplasm," was delivered by Dr Allen S Johnson (This lecture appeared in the May 27 issue of the *Journal*) The annual luncheon was served in Parlors A, B and C to 104 fellows

The second general session was held in the Georgian Room at 2 00 p m under the co-chairmanship of Dr W Richard Ohler and Dr Lewis M Hurxthal The Shattuck Lecture was delivered at 8 00 p m by Dr C Stuart Welch, of Boston, on the subject "Surgery in the Aged" (This lecture appeared in the June 10, 1948, issue of the *Journal*)

### WEDNESDAY, MAY 26

The third general session was held at 9 00 a m under the co-chairmanship of Dr Charles J Kickham and Dr Roy J Heffernan

At noon certain of the sections held their luncheons, followed by their annual meetings The Section of Medicine, under the chairmanship of Dr Francis C Hall, met in Parlor A The attendance was 142 The Section of Pediatrics, under the chairmanship of Dr Lewis W Hill, met in Parlor B, with 60 members in attendance at the luncheon and 75 at the scientific meeting following The Section of Radiology, under the chairmanship of Dr Hugh F Hare, met in Parlor C,

with 52 in attendance at the luncheon and 75 at the meeting The Section of Physiotherapy met in the Hancock Room under the chairmanship of Dr William D McFee, with 15 members present

At 2 00 p m the fourth general session was held in the Georgian Room, under the co-chairmanship of Dr William B Castle and Dr Stanley J G Nowak

The annual dinner was held in the Georgian Room at 7 00 p m with 456 in attendance The speaker of the evening was Mary Ellen Chase, Professor of English Language and Literature at Smith College, who delivered an address entitled "The Country Doctor on the Maine Coast"

### THURSDAY, MAY 27

The fifth general session was held in the Georgian Room at 9 00 a m under the joint chairmanship of Dr John J Poutas and Dr Claude E Welch

At noon the remaining scientific sections held their luncheons and meetings The Section of Surgery, under the chairmanship of Dr George S Reynolds, met in the Salle Moderne, with 140 in attendance The Section of Obstetrics and Gynecology met in Parlor A under the chairmanship of Dr Arthur T Hertig, with 50 in attendance The Section of Dermatology and Syphilology met in Parlor C under the chairmanship of Dr Austin W Cheever, with 38 in attendance The Section of Anesthesiology, under the chairmanship of Dr Urban H Eversole, met in Parlor B with 53 members attending

The sixth general session was held at 2 00 p m under the joint chairmanship of Dr John Fallon and Dr George S Reynolds

An exhibition of works of art by members of the Massachusetts Physicians' Art Association was on view throughout the meeting

The special list of officers, standing and special committees, councilors, censors, admissions and deaths is appended

H QUIMBY GALLUPE, *Secretary*

### ANNUAL MEETING OF THE SOCIETY

The one hundred and sixty-seventh annual meeting of the Massachusetts Medical Society was called to order by the president, Dr Edward P Bagg, in the Georgian Room of the Hotel Statler, Boston, at 11 00 a m, on May 25, 1948 Approximately 400 fellows were present

The Secretary submitted the record of the 1947 annual meeting, held on May 20, 1947, and pub-

frequently it may ultimately lead to glomerular degeneration, a constant by-pass of the cortical glomeruli with resulting ischemia and hypertension. Whereas the studies of Smith and his collaborators have made it difficult to maintain any theory of essential hypertension based on gross glomerular ischemia of any persistence, the possibility, of course, remains that circulation through specialized vessels not included or lost sight of in the usual clearance methods of measuring renal blood flow is the crucial factor in the origin of essential hypertension.

team of collaborators. Letters and queries are answered promptly, and there has been excellent co-operation with the other officers of the Society.

One of the epochal features of the transition stems from the change in by-laws that places the secretaryship on a full-time basis and in the scribe's hands responsibility for the work of his associates, the Director of Medical Information and Education and the Executive Secretary who pulls more than his own weight as office and business manager for the Society. In addition, Miss Gaston's Information Bureau, which has served such a useful purpose, has come under the Secretary's wing. Hereafter, all committee meetings will be cleared through him so as to prevent duplication in dating and accommodations.

In this manner, a continuity of policies and a proper regard for essential details not only will be attained but also will no longer depend upon officials who change from year to year. The presidency from now on should be a less demanding office, particularly when that officer is domiciled out of Boston. Both the Society and the incumbents thereby will gain. The Secretary will sit with practically all the Society's many committees to give advice when asked and to keep track of the proceedings. However, he will have the right to vote at only a few of them so that his power cannot become too great and thereby reduce the Society to just another example of eastern democracy such as Tito vouchsafes to the Serbs, the Croats and the Slovenes.

On July 1, 1947, the staid old Massachusetts Medical Society definitely broke with the past for the sake of improving public relations. The swift advance and dissemination of new facts in science during the twentieth century had effected a partial eclipse in the prestige of the medical practitioner. He himself was so busy meeting the demands of ailing fellow citizens and attempting to keep abreast of discoveries that cults and professional social workers were usurping his prerogative of preserving the health of the nation. Press relations were poor and legislators often were not much impressed with the doctor or what they conceived to be his motives. Smaller groups with more efficient organization were getting the attention and the votes.

In less than one year, I am glad to report, thanks to our energetic Director of Medical Information and Education, the situation, if not completely reversed, is greatly improved. The press now has ready access to facts and can check news items with authority before publication, and columns are open to us with unaccustomed liberality. The ink was scarcely dry on John Conlin's public-health diploma before he was in full swing in his new office. In less than six months he so hedged himself in with files, clippings and telephone calls than an expert stenographer, a press assistant and a sound scriber that could function at all hours were rushed to the rescue. His inspired management of the "pound law" campaign need not be re-told here, but the public as well as the legislators have once more come to understand that the medical profession, as a whole, is not venal or self-centered, and that the Massachusetts Medical Society's chief purpose is to further medical education and so to improve the standards of practice and to further the prevention of disease for one and all. Proud as I am of John's beginning, I have reminded him that the flesh has limitations and asked him hereafter not to spread himself too thin for efficiency in attacking important issues.

It is a pleasure to acknowledge the large debt of gratitude that we all owe to the ever-willing, always agreeable and yet astute Bob Boyd, who reserves the accommodations, satisfies hotel managers or hires perfect office girls all in his day's work. He has dealt so fairly with exhibitors that our display space is always oversubscribed by representatives who declare that they will come to Boston by preference so long as they can do business with our Robert. The balance sheet of the New England Postgraduate Assembly always shows black figures because we lend our business manager. More power to him, say I, and sometime soon more pay!

Those of you who have had occasion to sample the work of our stenographers know how well the officers and the interests of the Society have been served by the Misses Biggs, Kelly and Adler. They have outdone themselves in speed and accuracy during this transition period

with a most commendable spirit of friendly co-operation in spite of many new faces, new problems and new equipment. With their help also, the excellent 1947 *Directory* was compiled in the midst of the turmoil.

Such, then, is the state of the Society at the present writing. The sedate mid-Victorian styling has been replaced with the "New Look" of the mid-twentieth Century. Heaven forefend that coming modes should drive her again to straight lacing and waspishness. Naturally, it costs more today to keep our Alma Medica as she should be kept. Our dues, as you know full well, have more than doubled. To what ends, you may ask with justice, and with what results?

Of course, quite a number of resignations were prompted by the receipt of this year's bills. But most of these fellows already had reached retirement age and most of the others were residents outside Massachusetts. It is a sad commentary on the assiduity with which the *New England Journal of Medicine* is read to report that the Treasurer received not a few irate queries regarding his authority, his intentions and why in blazes he should need more pay. In spite of all this, our membership continues to grow, having surpassed 6500, and more members had paid their assessments before the March 1 deadline than did so in 1947. Thanks to this splendid record, more than \$22,000 has been turned over to the Boston Medical Library to assist in making more accessible one of the world's choicest collections of medical information. The new directors representing the Massachusetts Medical Society are already aiding in allocating this much-needed fund to best advantage.

A special committee is looking into the question of how we may assist the widows and dependents of fellows who have come upon hard times, as was originally recommended in partial justification of higher dues. Furthermore, in accordance with instructions, twice as much money was returned to the district societies this year.

Advances in pay for the employees in our office, together with retirement policies, have been put into effect according to previous authorization. The result was a considerable increase in our overhead expenses.

To cap the climax, the Commonwealth of Massachusetts now insists that we must pay the employment security tax on our own employees and those of the *Journal* retroactive to the middle of 1944, so that the financial status of the Massachusetts Medical Society may not prove to be so roseate as anticipated with the January 1 increase. The Treasurer may still find himself "standing in the need of prayer," if not of monies.

The reports of the numerous committees speak for themselves, but I should like to reiterate my admiration for the committeemen whose patience, ability and ready co-operation have opened my eyes during this enlightening year. Friendships formed in sharing assignments have more than compensated for the inevitable sacrifices and for geographic and meteorologic aggravations that impeded our efforts.

It is regrettable that the solution of the special services' problem was thwarted by economic considerations and the widespread lack of up-to-date hospital cost accounting. At least the definitions have been made clear and are widely distributed. Fellows who serve on individual hospital staffs must implement them locally wherever possible.

Judging from latest reports, there is small likelihood of the passage of compulsory health legislation in the current session of Congress, but this too is a problem that must continue under constant scrutiny.

Perhaps the most urgent item of unfinished business is that of our new headquarters, made more so by the need of the Medical Library for larger space. All year long Chairman Frank Ober has verged on but actually never achieved the gladsome report of a real-estate transfer that would provide us with a more suitable meeting place and rooms in which committees may function. If we do not acquire better accommodations soon, the proportion of district representation must be reduced. Otherwise, councilors will not have room to masticate the Cotting lunches, let alone hold rational converse with one another.

To these few admonitions, I join the best of wishes for the success of the incoming regime. The new officers

lished in the August 28, 1947, issue of the *New England Journal of Medicine*, and moved its acceptance. The motion was seconded and so voted.

President Bagge brought up the matter of the amendments to the by-laws and stated that in the printed form mailed to the fellows two mistakes had been noted at the Council meeting on the previous day—namely, the use of "Inc" following the two appearances of "The Massachusetts Medical Service"—and that these should be omitted. He also noted the omission of the Vice-President in the list of officers.

Dr. Bagge then read Article II of the Articles of Incorporation of the Society.

The Fellows of said Society shall have full power and authority to make and enact such rules and by-laws for the better government of the said Society as are not repugnant to the laws of this Commonwealth, and to annex reasonable fines and penalties, etc. The Fellows at their Annual Meeting, whenever such a number shall be present as the regulations of the Society may require [being 100, and there are 100 present] may revise, alter, enlarge, and repeal the by-laws of the said Society as the major part of the Fellows present may see fit, and not otherwise.

He then urged the adoption of these amendments (Appendix No. 1), that the work of the Society might be carried on more successfully.

The Secretary moved that the amendments to the by-laws, with the corrections already noted and made, be adopted. The motion was seconded.

Dr. Carl Bearse, Norfolk, then noted two more omissions as follows: Chapter VI, Section 4 under duties of the Secretary, "he shall perform such other duties as the Society or the Council may require," and again under Chapter VI, Section 7, under duties of the Executive Secretary, "he shall hold office at the pleasure of the Executive Committee."

Stressing the point that a committee should screen by-law changes and that the proposed changes were not urgent, Dr. Bearse moved that they be tabled until the next annual meeting. The motion was seconded. Dr. Bagge said that the motion was not debatable and asked for a show of hands. The Secretary counted and reported the motion carried.

Dr. Bagge registered his disapproval of the action and said he wished that the by-law changes could have been adopted.

Dr. Elmer S. Bagnall, Essex North, said that he believed that the fellows did not realize, when they voted, what the conditions would be and moved reconsideration. The motion was seconded and on a show of hands the motion was carried.

Dr. Albert A. Hornor, Suffolk, then asked for a reading of the motion to be re-considered. (The motion was read.)

Dr. Dwight O'Hara, Middlesex South, moved the adoption of the by-laws as amended. The motion was seconded.

Dr. Bagge then asked for the inclusion of the omissions as related by Dr. Bearse above. It was moved and seconded that these inclusions be made. It was so voted.

The Secretary reported on the membership of the Society as follows:

In May, 1947, the membership of this Society was 6256. There was a gain of 403 new members, and 9 re-instatements, making a total of 6668. Our losses consisted of 88 deaths, 35 resignations and 7 deprivations. The total membership in the Society, as of May 22, 1947, is 6538.

The Secretary then commented upon the *Directory* of the Society as follows:

The *directory* now in use was published last year and is correct as of July, 1947. It has in it all the information concerning the membership of the Society that the Society deems essential, and is issued under the direction of the Committee on Publications. The *directory* is available to members of the Society on request, and extra copies may be obtained by purchase from the office of the Society.

At the request of the President, the vice-president, Dr. Charles J. Kichham, Norfolk, assumed the chair and Dr. Bagge gave the following address:

The twelve months just completed undoubtedly will be judged in historical perspective as a period of transition for the Massachusetts Medical Society. In the loss just previously of our exceptionally able secretary, Michael A. Tighe, a severe handicap was imposed upon the efficient conduct of the Society's business, because he carried so many of the important details in his head. Coincidentally, the office assistant on whom he in turn had leaned was compelled by ill health to leave our employ.

However, President Dwight O'Hara, as his parting contribution, furnished the Society and the incoming regime with a capable new Secretary, Joseph Garland. The latter was courageous enough to accept the challenge to do what he could to put our affairs in order. You yourselves know how well he succeeded at no small sacrifice to himself. But I can assure you, from the point of view of harassed presidential inexperience, that his willingness and patience were exceeded only by his good nature and all-around reliability. Somehow we survived that first council meeting, though the margin was slim.

And then in September a second severe blow again deprived the Society of a highly esteemed fellow, the able editor of the *Journal*, Robert N. Nye. Once more the secretaryship fell vacant when the Committee on Publications elected Joseph Garland to succeed him as editor-in-chief. The latter long had been interested and associated in the editing of the *Journal* and naturally chose to devote his full time to publishing rather than recording the minutes and managing presidents for the Society. There really was no question in his mind or in mine about how the interests of the Massachusetts Medical Society would best be served, so that genial Joseph was released unconditionally to reactivate the blue pencil.

In behalf of the entire membership, hearty thanks are hereby extended to our new editor and erstwhile secretary for his prompt and loyal endeavors to help us in whatever role that was assigned to him.

When the availability of H. Quimby, Gallupe became known, his fine record in rectifying the disordered affairs of the Board of Registration in Medicine as secretary, and his wide acquaintance with medical practitioners of Massachusetts both in and out of the Society gained in this way, prompted his appointment early in December as secretary *pro tempore*. His nomination last month for the position of full-time secretary bears witness to the satisfactory character of his temporary ministrations. Under his supervision, the routine business of the Society now is handled with a minimum of friction by a superior

## APPENDIX NO 1

## AMENDMENT TO BY-LAWS

To be approved by Annual Meeting of Council on May 24, 1948

To be presented to the Massachusetts Medical Society at Annual Meeting to be held on May 25, 1948

## CHAPTER IV, Section 1

The Council shall consist of councilors chosen by the district societies, the president, vice-president, ex-presidents, president-elect, vice-presidents ex-officio, secretary, treasurer, and assistant treasurer of the Society, the secretaries of the district societies, the chairmen of all standing committees, the editor of the *New England Journal of Medicine*, the president of the Massachusetts Medical Service, if he be a physician and a member of this Society and the medical director of the Massachusetts Medical Service, if he be a member of this Society

## CHAPTER IV

## APPOINTMENT OF DIRECTOR OF MEDICAL INFORMATION AND EDUCATION

Section 8 The Council may appoint and dismiss a Director of Medical Information and Education

## SALARIES AND APPROPRIATIONS

Section 9 The Council shall vote the salaries of its officers and employees, shall determine the tenure they may respectively have in their offices, the appropriations for its officers, employees, and committees, and such other appropriations as it deems suitable

No officer, employee, or committee shall exceed the voted appropriation

No salary to any officer or employee and no regular appropriation shall be increased except on recommendation of the Committee on Finance and by vote of the Council

The Treasurer is authorized, on recommendation of the Committee on Finance, to pay such monies as may be necessary in the event of emergency, the existence of which shall be determined by the President.

## CHAPTER VI OFFICERS

## DUTIES OF SECRETARY

Section 4 The Secretary shall attend all meetings of the Society, the Council and the Executive Committee, and shall record their respective proceedings in separate volumes

He shall cause to be engrossed and shall sign the diplomas of new fellows, if satisfied that they have met the requirements of Chapter I, and shall issue all diplomas and certificates of fellowship

He shall notify fellows of votes by the Council or Executive Committee granting permission to retire, to resign, to transfer district membership or to have dues remitted, and of votes depriving them of or reinstating them in the privileges of fellowship

He shall be *ex officio* secretary of all boards of trial, the Board of Supervising Censors, the Committee on Publications, the Committee on Ethics and Discipline, and the Committee on Membership, and shall keep the records of each in separate volumes. He shall be a member *ex officio* of all other committees without power of vote

He shall notify members of committees of their appointment and of the duties assigned them. On advice of their chairman or secretary he shall give due notice of the time and place of their several meetings

He shall have custody of the seal of the Society and of all books, papers, manuscripts, prints and paintings belonging to the Society, except such as are in charge of the Treasurer

He shall issue notices of the meetings of the Council according to such rules as the Council may adopt. He shall issue to every fellow one month before the annual meeting of the Society a program, listing the time and place of that meeting and of the stated meetings of the

Council, the boards of censors for that year, and information concerning the payment of assessments and the distribution of publications, if there are any proposed amendments of the by-laws, he shall provide that each program is accompanied by a copy thereof

He shall transfer fellows from one district to another under the terms of Chapter III, Section 3, and shall report to the Society at its annual meeting the changes in membership during the year

He shall conduct official correspondence and shall notify officers and delegates of their appointments and of their duties

He shall keep a directory of the fellows, and shall publish the same, under the direction of the Committee on Publications, at such intervals as may be determined by the Council. He shall furnish this on request to fellows not in arrears

He shall have jurisdiction over the work of the Executive Secretary and over the work of the Director of Medical Information and Education

He shall perform such other duties as the Society or the Council may require.

## DUTIES OF EXECUTIVE SECRETARY

Section 7 The Executive Secretary, under the jurisdiction of the Secretary, shall assist the officers, the Council and such committees as may request his services. He shall also serve as manager of the general office, and shall help in the arrangement of the annual meeting and of such other meetings as are sponsored in whole or in part by the Society

He shall hold office at the pleasure of the Executive Committee.

## DUTIES OF DIRECTOR OF MEDICAL INFORMATION AND EDUCATION

Section 8 The Director of Medical Information and Education, under the jurisdiction of the Secretary, shall promote, in an ethical manner, the educational usefulness of the Society to the fellows, to all licensed physicians in Massachusetts and to the public. He shall also assist the officers, the Council and such District Societies or committees as may request his services

## EXPENSES OF OFFICERS, EXECUTIVE SECRETARY, DIRECTOR OF MEDICAL INFORMATION AND EDUCATION, AND COMMITTEES

Section 9 The traveling and incidental expenses of the officers, of the Executive Secretary, of the Director of Medical Information and Education, of the committees of the Society elected by districts, and of other committees of the Society, on request, shall be paid by the Treasurer, on presentation of an itemized bill duly approved by the President.

These amendments were favorably acted upon by the Executive Committee of the Council on April 7, 1948

## APPENDIX NO 2

## OFFICERS FOR 1948-1949

President Daniel B Reardon, Quincy, 1186 Hancock St  
President-Elect Arthur W Allen, Boston, 266 Beacon St  
Vice-President Donald Munro, Milton Office, Boston, Boston City Hospital  
Secretary H Quimby Gallupe, Waltham Office, Boston, 8 Fenway  
Treasurer Eliot Hubbard, Jr, Cambridge, 29 Highland St  
Assistant Treasurer Norman A Welch, West Roxbury Office, Boston, 520 Commonwealth Ave  
Orator C Sidney Burwell, Brookline Office, Boston, 25 Shattuck St

## COMMITTEES ELECTED BY THE DISTRICTS

Executive Committee of the Council — Established 1941 (members *ex-officio* and one councilor and alternate elected by the councilors of each district medical society)  
PRESIDENT Daniel B Reardon, Quincy, 1186 Hancock St  
PRESIDENT-ELECT Arthur W Allen, Boston, 266 Beacon St

will find, as their predecessors found, that new problems will arise soon enough and frequently. I have full confidence that we are well set to meet whatever contingencies may arise.

Hippocrates, our father in medicine, composed the following precept (Chapter XII) "If for the sake of a crowded audience, you do wish to hold a lecture, your ambition is no laudable one, and at least avoid all citations from the poets." Accordingly, let me close this report in heartfelt prose. Fellows of the Massachusetts Medical Society, for the honor and privilege of serving you, I am deeply grateful.

Dr. Bagg resumed the chair and asked the Secretary to read the list of those fellows who joined the Society in 1898 and were still active, and requested those present to come forward and receive a gold pin as a memento to remember the occasion.

The Secretary read the following list of names:

Dr. George S. C. Badger, of Boston  
 Dr. Daniel C. Dennett, of Winchester  
 Dr. Clara P. Fitzgerald, of Worcester  
 Dr. Walter W. Fullerton, of Brockton  
 Dr. Joseph A. Hogan, of Lawrence  
 Dr. Myron L. King, of Cambridge  
 Dr. George C. Littlefield, of Webster  
 Dr. Alverne P. Lowell, of Fitchburg  
 Dr. Harry W. Luchsinger, of Great Barrington  
 Dr. George F. MacKay, of Dalton  
 Dr. William V. McDermott, of Salem  
 Dr. William D. McFee, of Haverhill  
 Dr. Harris P. Mosher, of Marblehead  
 Dr. Marion Nute, of Brookline  
 Dr. Joseph H. Pratt, of Boston  
 Dr. Jane D. K. Sabine, of Boston  
 Dr. Frederick W. Stetson, of Boston  
 Dr. Peter H. Thompson, of Boston

The Secretary then offered the following motion:

According to Chapter I, Section 4, of the by-laws, two fellows of the Society, namely, Dr. Bagg and Dr. Gallupe, have nominated Sir Reginald Watson-Jones as an honorary fellow. This has been confirmed by the Committee on Membership and by the Council yesterday.

According to Chapter I, Section 4, this confirmation should have been made at a previous stated meeting of the Council, but it was impossible to do so, owing to lack of time or sufficient foresight.

I move that, according to Article 2 of the Articles of Incorporation, this meeting alter the by-laws temporarily, that the granting of this fellowship may be made possible.

Dr. Bagnall seconded the motion, and it was so voted.

Dr. Gallupe moved that the Massachusetts Medical Society designate Sir Reginald Watson-Jones as honorary fellow. The motion was seconded.

Dr. Bagg spoke as follows:

I won't allow discussion of that. All those in favor, please say Aye. Those opposed, no. It is a vote. I have

delegated Dr. Russell Sullivan as a proxy to bring the recipient to the dais.

Honored Fellow, if your knowledge of Latin is as great as ours, I am prepared to furnish you with a translation of what is inscribed on your diploma. I shall read it.

"Whereas it is usual for a Society devoted to the furtherance of medicine to elect to fellowship men of productive scholarship in this art, the Medical Society of the Commonwealth of Massachusetts, founded A.D. 1848, designates as Honorable Fellow Honorable Sir Reginald Watson-Jones, a man of recognized attainment in advancing the interests of science, and accords him all the privileges of the Society. The Society would express its desire that the recipient of this honor may communicate in the form of papers any original contributions made by him to the art of medicine. In token whereof the Council have ordered this Seal of the Society to be affixed at Boston, Massachusetts, May 25, A.D. 1948, and in the one hundred and seventy-second year of the independence of the United States of America."

I welcome you into fellowship.

Sir Reginald Watson-Jones replied as follows:

I am sorry that this election caused some little disturbance in the matter of the by-laws, but I am very glad that the by-laws situation was resolved so easily and smoothly. I can't tell you how deeply I appreciate the very great honor conferred upon me, the honor of being numbered among the very select few honorary fellows of this oldest medical society in the United States.

Whenever I make any contact with Boston, it seems to me that my friendships with the men of this city, the surgeons of this city and the doctors of this city, increase every time. My first contact was twenty-five years ago. I came here as an extremely unknown, unheard of man as a ship's surgeon on one of the Cunard ships, and I was received in the city as if I were a great leader of surgery. I was even taken out to a clam bake. And every year since then, the number of my friends and the closeness of my friendship with those friends has increased.

This great honor that you have done me is one mark of the warmth of friendship between surgeons on the two sides of the Atlantic. And I have only one hope, sir, and that is that in due course — I believe I can just make it — I may attend here to receive from the hands of the President of 1998, the medal of fifty years' membership in the Society.

The President then called for the delegates from the New England State Medical Societies. Dr. Robert A. Goodell, of Connecticut, responded as follows:

I do not know whether I am the only representative from the New England States, but I wish to have the honor and privilege of bringing you greetings from the Connecticut State Medical Society. Dr. James R. Miller, the retiring president, and Dr. Harvey, the president-elect, both wish me to extend greetings and best wishes, and I am sure that I am doing that also for the entire Society. I wish to congratulate you on your splendid program, and I trust if any of you have the opportunity to visit the meeting of the Connecticut State Medical Society, you will receive as cordial and as gracious a welcome as I have received here.

The President then introduced the incoming officers, after which the one hundred and fortieth annual oration, "The Responsibility of Medicine in the Propagation of Poor Protoplasm," was delivered by Dr. Allen S. Johnson, of Springfield.

Dr. Bagg then declared the one hundred and sixty-seventh annual meeting of the Massachusetts Medical Society adjourned at 12:30 p.m.

Thompson, Jr., Fitchburg, *executive councilor*, John J. Curley, Leominster, *public relations councilor*, James V. McHugh, Leominster, *legislative councilor*, C. Bertram Gay, Fitchburg

### ADMISSIONS RECORDED FROM MAY 22, 1947, TO MAY 22, 1948

YEAR OF ADMISSION	NAME AND RESIDENCE	MEDICAL SCHOOL
1947	Abbott, Richard N., Natick	Yale
1947	Abdu, Louis, Brockton	Tufts
1947	Abrams, Arthur L., Brookline	Harvard
1948	Alexander, Daniel David, E. Gardner	Middlesex
1948	Altenhaus, George, Rutland	University of Vienna
1948	Anderson, Ernest G., Belmont	Friedrich Wilhelm University, Berlin
1947	Appel, Charles F., Cambridge	Jefferson Medical College
1947	Armstrong, Beverly, Brighton	Syracuse University
1948	Armstrong, Catherine, Wellesley	University of Vermont
1948	Arnot, Robert E., Brookline	Harvard
1947	Avola, Francis A., Medford	Tufts
1948	Bacastow, Merle S., Worcester	University of Pennsylvania
1947	Ballantine, Henry T., Jr., Brookline	Johns Hopkins University
1947	Barger, A. Clifford, Brighton	Harvard
1948	Barlan, Donald B., Lynn	Boston University
1947	Barnes, John D., New Bedford	University of Maryland
1948	Barnes, William E., Taunton	Tufts
1948	Barnes, William L., Lowell	Middlesex
1947	Barone, Henry, Newton	Middlesex
1947	Barry, John J., Chelmsford	Middlesex
1947	Beer, Ernest G., Lowell	University of Heidelberg
1947	Belinkoff, Stanton, New Bedford	Middlesex
1948	Bell, William R., Marblehead	Yale
1948	Belock, John E., Beverly	University of Vermont
1947	Bergan, Carl A., Lenox	Middlesex
1948	Berman, Samuel S., Roxbury	Middlesex
1947	Bernstein, Joseph I., Springfield	Middlesex
1948	Bill, Alexander H., Jr., Boston	Harvard
1948	Bilski, Theodore D., Westfield	University of Halle, Germany
1948	Blacklow, Daniel J., Cambridge	Tufts

1948	Leard, Samuel E , Boston	Boston University
1948	Leary, Gerald C , Westwood	Tufts
1947	Leavell, Hugh R , Cambridge	Harvard
1948	Lec, Charles F , Andover	Middlesex
1947	Levine, Sidney A , Melrose	George Washington University
1947	Lewis, Emery C , New Bedford	University of Vermont
1947	Licht, Sidney, Cambridge	New York University
1948	Lichty, Joseph S , Brookline	Harvard
1947	Lief, Philip A , Roxbury	New York University
1947	Lingos, John W , Brockton	Middlesex
1948	Lockshin, Abraham D , Medford	Middlesex
1948	Loeb, Elsie K , No Attleboro	University of Munich
1947	Lucacer, Michael, Cambridge	Royal University, Palermo, Italy
1947	Lynch, J P , Jr, Marlboro	Boston University
1947	MacKenzie, Michael V , Medford	Tufts
1947	Madoff, Irving, Clinton	New York University
1948	Maffeo, Peter A R , E Boston	Tufts
1947	Maison, George L , Needham	Northwestern University
1948	Malone, Edward H , Waban	Boston University
1947	Manning, John J , Worcester	University of Pennsylvania
1948	Martens, Theodore G , Fall River	University of Rochester
1948	Martin, Francis, Boston	Queens University, Canada
1947	Massik, Paul, Dorchester	Tufts
1948	Maynard, Guv B , Jr, New Bedford	Cornell University
1947	Mayo, Frederic B , Swampscott	Cornell University
1948	Mayo, Walter V , Kingston	Middlesex
1948	McCarter, Robert H , Boston	Jefferson Medical College
1947	McCarthy, Francis D , Melrose	Tufts
1948	McDermott, John R , Boston	Yale
1947	McEneaney, Joseph P , Lawrence	Boston University
1947	McEnroe, Donald F , Whitman	Middlesex
1947	McGinty, John F , Jr, Lawrence	Jefferson Medical College
1947	McKernan, Bernard F , Upton	Middlesex
1947	McLean, Donald E , Winchester	Harvard
1947	McMahon, Francis J , Holbrook	Boston University
1948	McManama, John C , Waltham	Tufts
1948	McVay, John F , Dedham	Tufts
1947	Meilman, Edward, Boston	Harvard
1947	Meilin, Jacob, Bedford	University of Lausanne

### CASE 34311

#### PRESENTATION OF CASE

A seventy-five-year-old Negro was admitted to the hospital complaining of pain in the right flank.

About six years before admission the patient began having superficial pain in the right lower thigh. No other accompanying signs or symptoms were noted. Four months before admission there was sudden weakness of the right leg, and standing caused severe pain. Since then he had been unable to walk. There was no joint pain, chills or fever. About two months before admission there was occasional mild right-flank pain, which did not bother the patient unduly. Defecation and urination were normal at that time, and there were no gastrointestinal symptoms. The pain later became severe and persistent and occasionally radiated to the right groin. The patient's wife stated that he had had black stools. She also stated that he had been under treatment for "high blood pressure" for four years and that eight weeks before admission he had an episode of very labored breathing. He had had an easily reducible right scrotal hernia for fifty years.

Physical examination revealed a poorly nourished, confused, dyspneic and acutely ill man. The veins of the scalp and neck were engorged but not pulsating. The lungs were emphysematous. Medium moist rales were heard throughout both bases. The right leaf of the diaphragm was much elevated and showed limited excursion. The heart was enlarged to the left. A Grade II systolic murmur was heard over the whole precordium. There was moderate distention of the abdomen, and peristalsis was normally active. Voluntary resistance was

encountered over the right flank, which was filled by a tender, poorly defined mass. Little, if any, costo-vertebral angle tenderness was elicited. Rectal examination revealed tenderness on the right. The prostate was slightly enlarged and nodular. A large, right scrotal mass was present, in which gurgles were heard. There was superficial and deep tenderness on the anterior aspect of the right thigh. Knee jerks were normal. No edema was present.

The temperature was 97.5°F, the pulse 90, and the respirations 22. The blood pressure was 100 systolic, 68 diastolic.

Examination of the blood revealed a white-cell count of 23,000, with 88 per cent neutrophils, and a red-cell count of 4,000,000. The hemoglobin was 12 gm. The urine had a specific gravity of 1.019 and contained + albumin. No casts were seen, but the sediment was "loaded" with leukocytes. The stool was brown and had a ++ guaiac reaction. The nonprotein nitrogen was 42 mg, the serum calcium 7.7 mg and the phosphorus 3.0 mg per 100 cc. The alkaline phosphatase was 4.8 and the acid phosphatase 1.4 units per 100 cc. The total serum protein was 5.7 gm per 100 cc. The chloride was 94 and the carbon dioxide 21.2 milliequiv per liter.

X-ray examination of the chest showed an elevated diaphragm, linear streaks of atelectasis at the right base, enlargement of the heart, and elongation and tortuosity of the thoracic aorta. No free air was seen beneath the diaphragm. There was extensive Paget's disease involving the pelvis and lumbar spine. A diffuse increased density was seen in the right side of the abdomen. Neither kidney contour was visualized, and the right psoas shadow was not present. There was a single large calcification, about 1 cm in diameter, and several smaller calcifications superimposed on the right kidney shadow. Calcification was seen in the abdominal aorta. An excretory urogram revealed an essentially normal left upper urinary system. No dye was excreted from the right kidney. A barium enema was negative except for the scrotal hernia, which contained cecum and small bowel. A retrograde pyelogram was attempted but the catheter would not pass up the ureter more than 0.5 cm. No efflux was seen from either orifice.

On the fourth hospital day an operation was performed.

DR WYMAN I do not believe that it is safe for us to say that the kidney on the right is displaced laterally. There is a faint hint from the available films that it is farther lateral than usual. The position of the stone is more lateral than one would see with pelvic stone.

DR YOUNG Is there a chance that this mass of which you speak and which I have disregarded could be an aneurysm?

DR WYMAN I was thinking of that, but I cannot outline calcium in it with any degree of certainty. There is a fair amount of calcium lying up here. I do not know what it is.

DR YOUNG The description does not suggest that the mass pulsated.

DR WYMAN I wondered about an aneurysm of the renal artery or some such thing pushing the kidney up.

DR YOUNG It did not pulsate.

#### CLINICAL DIAGNOSIS

Calculus pyonephrosis

#### DR YOUNG'S DIAGNOSIS

Calculus pyonephrosis

Tumor of kidney?

Tuberculosis of kidney?

#### ANATOMICAL DIAGNOSES

*Retroperitoneal fibrosarcoma, with pressure on right kidney, extension into inferior vena cava, duodenum, and ascending colon, and with metastases to lung*

Perinephritis, acute, chronic

Peritonitis, acute

Operation nephrostomy, right

#### PATHOLOGICAL DISCUSSION

DR BENJAMIN CASTLEMAN The kidney was explored through a right transverse incision and chronically inflamed perirenal tissue was encountered as the lumbodorsal fascia was opened. At that time aspiration of the tissue yielded thick, greenish pus. An incision was made through the kidney cortex into the pelvis and the stone, seen by x-ray, was removed. A nephrostomy tube was placed in the pelvis. At the time of operation a biopsy of some of this inflamed tissue around the kidney was taken on which a diagnosis of fibrosarcoma was made. The patient did not do well postoperatively and died a few days later.

At autopsy we found that the kidney was displaced a great deal, in fact, it lay almost horizontally. This horizontal position of the kidney was due to a large retroperitoneal mass in the right side of the abdomen which pushed the kidney up. Anterior to the mass was the ascending colon and medially and superiorly was the duodenum. They were both intimately connected by the mass, which had eroded through into their lumens. This ade-

quately explains the tarry stools noticed by the patient's wife and the positive guaiac test in the hospital. The mass was tremendous in size and proved to be a fibrosarcoma arising in the retroperitoneal space. A very interesting finding was an extension of the tumor into the inferior vena cava in a polypoid fashion. Microscopic sections of the surface of this polyp showed endothelium of the vena cava, so that the tumor was really pushing the vena cava ahead. The tumor did not arise within the kidney substance at all, the fibrous capsule of the kidney being clearly visible between renal parenchyma and tumor. The tumor had metastasized to the lung.

DR YOUNG You did not check the bone?

DR CASTLEMAN One section of bone showed no evidence of metastases. The pus that the operator had found at operation was due to the perforation of the ascending colon with spillage of fecal material.

DR YOUNG Between the tumor and the ascending colon?

DR CASTLEMAN Yes. At the time of autopsy that had extended up along the right gutter into the peritoneal cavity and had produced peritonitis on the right side.

DR YOUNG Did they get through to the kidney?

DR CASTLEMAN No, there was no stone in the kidney.

DR YOUNG But they got into the pelvis?

DR CASTLEMAN Yes, the nephrostomy tube was in the kidney pelvis, but the tumor had completely obstructed the ureter on that side.

DR YOUNG Did the tumor involve the nerve to cause the leg symptoms?

DR CASTLEMAN I cannot answer that. It might well have.

#### CASE 34312

#### PRESENTATION OF CASE

A seventy-one-year-old man entered the hospital because of an abdominal mass.

The abdomen had always been of rather extensive proportions, but three months before admission he noted a hard swelling on the right side which did not change appreciably in size following discovery. His appetite was always good although for three years he was bothered by increasing belching following meals. There was never any food intolerance, abdominal pain or vomiting. His diet had always been good. Gradually increasing constipation also bothered him during the three years before admission, although there was no change in the character of the stools and never any diarrhea. There were never any symptoms of liver disease and no weight loss.

The patient was born in Greece, where he was brought up on a farm. He came to the United States at the age of thirty-one and went to work in a shoe

## DIFFERENTIAL DIAGNOSIS

DR EDWARD L. YOUNG A medical man must have made the statement about the mass in the right flank. If it had been made by a trained urologist, he would have said whether or not it gave the impression of going through to the flank on ballottement, if it is kidney, there is generally the sensation that the mass goes through or close to the costovertebral angle.

The blood picture is surprisingly good for a man as sick as this.

Let us discuss the x-ray films at this point.

DR STANLEY M. WYMAN The heart is considerably enlarged, it looks to be chiefly left ventricular enlargement. The aorta is quite tortuous, especially in the descending portion, and there is some calcification in the wall. The ascending portion of the aorta appears dilated and may be dilated as far as the descending portion, although one cannot be sure of the latter. There is some atelectasis in the lower portion of the right lung field. I cannot localize it because there is no lateral view. The humerus shows some changes quite consistent with Paget's disease. The films of the abdomen show the area of calcification described, overlying the right kidney, in the lateral view it is seen to lie far posteriorly, again coincident with the kidney. I cannot outline the kidney itself on either side with any degree of certainty. The intravenous dye is excreted by the left kidney in fair concentration, and the major and minor calyces are grossly normal so far as can be determined. The kidney appears approximately normal in size. There are several films that show a faint linear shadow in the region of the right kidney, which makes me wonder if it could be the medial margin of the kidney. If so, the kidney is displaced laterally. However, this is not certain enough to make any definite statement. There is a well defined arc of calcification just to the left of the lumbar spine, which in the lateral view is seen to be a considerably dilated abdominal aorta. The bones of the lumbar spine and pelvis are normal.

DR YOUNG Are you sure that what you see in the bones is Paget's disease and not metastases?

DR WYMAN I think it is Paget's disease.

DR YOUNG Are you always able to differentiate?

DR WYMAN No. The differential point is the increased size of the bone and the involvement chiefly of the cortex. These are fairly definite in this particular person. The thickening in the ilium lies along the margin and inner aspect of the pelvis. Paget's disease is more likely than osteoblastic metastases.

DR YOUNG Will you comment on the reason why you think there is stone in the kidney?

DR WYMAN The character of the calcification is rather discrete. It is not homogeneous but mottled. It lies far posteriorly, at the expected

location of the kidney itself. All these add up to make it more likely to be a kidney stone than a calcified lymph node or a gallstone. I think the shadow in the right flank, which is described in the protocol, may represent the colon filled with fluid because on the barium enema there is a large loop of colon overlying the ilium, and one can see a big hernial sac containing cecum and ileum.

DR YOUNG The whole picture seems to me to be somewhat confusing. We have an old man who is sick. The pain in his leg may have been due to hypertrophic changes, which are usually seen in the spine in a man of seventy-five, or to Paget's disease. The black stools are difficult for me to put into the picture. That statement was made by his wife but apparently no attempt was made to find out whether medication had been given that might have caused them. We are not sure that they were due to blood. He was treated for high blood pressure four years ago—and yet he comes in with a blood pressure far below what is expected. We can attribute that to his poor general condition. He has a leukocytosis, a mass in the right flank, a shadow that suggests kidney stone, and pus in the urine. The right ureter could not be catheterized. That does not necessarily mean that it was completely blocked. It often is difficult to catheterize the ureter because of stiffness—when actually there is a passageway through it. The white count suggests that there was infection going on even though he had no temperature. The other kidney was working. The specific gravity was 1.019. The nonprotein nitrogen did not show much elevation, in fact, 42 mg would be within high normal limits.

The first thought here would be a calculus pyonephrosis, but one must remember that although tuberculosis of the urinary tract almost always shows itself in bladder irritation, it occasionally occurs without it. It is not impossible that there is a background here of tuberculosis and mixed infection, although that is not usual. We must not forget that tumor of the kidney can have a stone present. There was a negative barium enema, and I cannot seem to connect the blood in the stool with this unless we have a condition of congestion due to cardiac decompensation. So I think that this constitutes a calculus pyonephrosis, with or without one of the other two things being present. He is an extraordinarily poor risk because of what we know about his general condition, yet today with the ability we have to increase the body chemistry of the patient to a level more closely normal we can get away with what ten or fifteen years ago would have been murder. If this is calculus pyonephrosis, a two-stage operation may give him a chance. There may be something entirely different, but I will put calculus pyonephrosis as my first choice, with or without the other.

asymptomatic with a fairly large mass in his abdomen

Could we be wrong about the diagnosis? Unfortunately, yes. However, the mass is lobulated and apparently cystic — and I know of no other cystic mass that could grow to this size in the right upper quadrant without producing symptoms. Any solid mass of this size would undoubtedly produce symptoms. The mass was certainly cystic. Those who took care of him thought so because they describe it as fluctuant and went so far as to try to transilluminate it. If it did not involve the under surface of the right diaphragm one would have to consider such things as large multilocular pancreatic cysts — they grow to huge proportions. If it were on the left, a splenic cyst would have to be thought of, or an omental cyst. But under the circumstances there is nothing to indicate any other diagnosis but an echinococcus cyst.

How do you feel about it, Dr. Adams?

DR F DENNETTE ADAMS. I agree that it would be a job to get it out and the chances for spilling are great.

DR KRANES. The risk of spilling seems greater than the risk of leaving it alone. He apparently did well.

#### CLINICAL DIAGNOSIS

Echinococcus cyst

#### DR KRANES'S DIAGNOSIS

Echinococcus cyst

#### ANATOMICAL DIAGNOSIS

Echinococcus cyst

#### PATHOLOGICAL DISCUSSION

DR RONALD C SNIFFEN. The patient was operated on with a preoperative diagnosis of echinococcus cyst, and it was found that the cyst ran

from the pelvis up to the liver and occupied almost the entire right lobe of that organ. It was surrounded by peritoneal adhesions, and daughter cysts were noticed in the remaining liver. A partial excision of the cyst was performed and a drain was inserted into the remaining cavity. Microscopically the wall of the cyst showed the characteristic laminated chitinous membrane and germinative epithelium of an echinococcus cyst. It is now about two and a half months since operation. The patient is back at work and feels well, but a small amount of material is draining through the sinus in the right upper quadrant.

DR GRANTLEY W TAYLOR. The medical service wanted to have us carry out laparotomy in this case for confirmation of the diagnosis. Peritoneoscopy had been considered as an alternative method of investigation but it was felt that this would yield less positive findings. The operative findings have been described. Many of the cysts were thick walled and necrotic and contained opaque thick purulent-like material. Others were thin walled and contained clear fluid. Two or three basinfuls of these cysts were collected and cleansed to be used for antigen. My impression was that there had been previous minor ruptures of these cysts to account for the numerous adhesions and the dispersion which was present.

I cannot agree entirely with Dr. Kranes that there is no indication for operation because sometimes large cysts of this type are ruptured by relatively minor trauma and then constitute a real abdominal emergency. In addition I think that the record perhaps fails to emphasize that the pressure symptoms were reaching the point where they caused the patient considerable trouble, not only with the function of the gastrointestinal tract but in respiration as well.

factory. He continued in this business until admission to the hospital and was exposed to numerous types of chemicals. This exposure occasioned visits to the skin clinic of the hospital twice several years previously at which time diagnoses of contact dermatitis were made.

Physical examination showed a well developed but poorly nourished man. Examination of the chest was not remarkable except for a high relatively fixed diaphragm. The abdomen was large and asymmetrical. There was a fluctuant, non-tender, apparently lobulated mass, which moved with respiration and extended from the fourth intercostal space on the right to two inches below the umbilicus and could be felt in both flanks, being more prominent on the right. It could not be transilluminated. There were bilateral reducible inguinal hernias and bilateral varicoceles.

The temperature, pulse and respirations were within normal limits. The blood pressure was 148 systolic, 90 diastolic.

The blood, urine and stool tests were negative except for slight anemia, a hemoglobin of 11.5 gm, and a 10 per cent eosinophilia. The nonprotein nitrogen, fasting blood sugar, amylase, cephalin flocculation, van den Bergh, and bromsulfalein test, phosphorus, alkaline phosphatase, and prothrombin time were all within normal limits. The total protein was 8 gm per 100 cc, with an albumin-globulin ratio of 0.85. An x-ray film of the chest showed nodularity of the right diaphragm. A gastrointestinal series showed a negative esophagus, a stomach displaced to the left and posteriorly, and no intrinsic involvement of the gastrointestinal tract. It was thought that the mass was related to the liver. There were a number of calcifications in the upper portion of the liver. An echinococcus skin test was positive.

On the sixth hospital day an operation was performed.

#### DIFFERENTIAL DIAGNOSIS

DR ALFRED KRANES: There are two statements in the record to which I should like to take exception. One is the description of the mass, which is said to extend from the fourth intercostal space on the right to two inches below the umbilicus. I do not see how one can feel a mass of this size in the fourth intercostal space. What is meant is that the area of liver dullness extended up to the fourth intercostal space. I find it hard to believe that the mass could be felt that high, although that is the

impression one gets from the description. One can only say that the mass extended so far below the costal margin. The other statement that I question is the description by x-ray of nodularity of the diaphragm. I think what is meant is irregularity. One cannot say that the diaphragm is nodular, can one?

DR STANLEY M. WYMAN: No.

DR KRANES: That implies a third dimension which, of course, we do not have.

DR WYMAN: The radiologist's statement in the record was, "There is irregularity of the right leaf of the diaphragm resulting from nodularity or masses projecting from the superior aspect of the liver."

DR KRANES: That makes the diagnosis easier.

DR WYMAN: The right leaf of the diaphragm is definitely elevated and as you see comes to the fourth interspace. The lung fields otherwise appear intrinsically clear. The heart shadow is prominent toward the left, probably in the region of the left ventricle. The barium-filled stomach is faintly seen in this film displaced toward the left, and the duodenal cap is displaced downward and to the left. The entire right side of the abdomen is dense and there is a suggestion of several small areas of calcification. There is a very definite mass, nodular and lobulated, on the right.

DR KRANES: As I see this problem there is no differential diagnosis. What else can this be but an echinococcus cyst? If that diagnosis is correct, and I can see no other one to make, I must say that I would not have him operated on. You must remember that he is seventy-one years old. The disease started before the age of thirty-one and although he gave a history of having felt the mass only three months before entry, you will all agree, I am sure, that an echinococcus cyst of this size must have been growing for many, many years. Furthermore, despite its size, and it does seem to be huge, it has produced absolutely no symptoms. The record states that the man was feeling quite well except for a few mild symptoms of belching and constipation. Nor has it interfered with the function of any organ although it has displaced the stomach. While it may involve a fairly large part of the liver, it has not interfered with the liver's function or produced any alteration in the laboratory tests. They were all normal. Consequently, I probably would not have advised this patient to be operated on since I see nothing to be gained by operation at seventy-one on an asymptomatic echinococcus cyst. The chances are that he might have gone another five or ten years still.

asymptomatic with a fairly large mass in his abdomen

Could we be wrong about the diagnosis? Unfortunately, yes. However, the mass is lobulated and apparently cystic — and I know of no other cystic mass that could grow to this size in the right upper quadrant without producing symptoms. Any solid mass of this size would undoubtedly produce symptoms. The mass was certainly cystic. Those who took care of him thought so because they describe it as fluctuant and went so far as to try to transilluminate it. If it did not involve the under surface of the right diaphragm one would have to consider such things as large multilocular pancreatic cysts — they grow to huge proportions. If it were on the left, a splenic cyst would have to be thought of, or an omental cyst. But under the circumstances there is nothing to indicate any other diagnosis but an echinococcus cyst.

How do you feel about it, Dr. Adams?

DR. F. DENNETTE ADAMS: I agree that it would be a job to get it out and the chances for spilling are great.

DR. KRANES: The risk of spilling seems greater than the risk of leaving it alone. He apparently did well.

ANATOMICAL DIAGNOSIS

Echinococcus cyst

PATHOLOGICAL DISCUSSION

DR. RONALD C. SNIFFEN: The patient was operated on with a preoperative diagnosis of echinococcus cyst, and it was found that the cyst ran

from the pelvis up to the liver and occupied almost the entire right lobe of that organ. It was surrounded by peritoneal adhesions, and daughter cysts were noticed in the remaining liver. A partial excision of the cyst was performed and a drain was inserted into the remaining cavity. Microscopically the wall of the cyst showed the characteristic laminated chitinous membrane and germinative epithelium of an echinococcus cyst. It is now about two and a half months since operation. The patient is back at work and feels well, but a small amount of material is draining through the sinus in the right upper quadrant.

DR. GRANTLEY W. TAYLOR: The medical service wanted to have us carry out laparotomy in this case for confirmation of the diagnosis. Peritoneoscopy had been considered as an alternative method of investigation but it was felt that this would yield less positive findings. The operative findings have been described. Many of the cysts were thick walled and necrotic and contained opaque thick purulent-like material. Others were thin walled and contained clear fluid. Two or three basinfuls of these cysts were collected and cleansed to be used for antigen. My impression was that there had been previous minor ruptures of these cysts to account for the numerous adhesions and the dispersion which was present.

I cannot agree entirely with Dr. Kranes that there is no indication for operation because sometimes large cysts of this type are ruptured by relatively minor trauma and then constitute a real abdominal emergency. In addition I think that the record perhaps fails to emphasize that the pressure symptoms were reaching the point where they caused the patient considerable trouble, not only with the function of the gastrointestinal tract but in respiration as well.

factory. He continued in this business until admission to the hospital and was exposed to numerous types of chemicals. This exposure occasioned visits to the skin clinic of the hospital twice several years previously at which time diagnoses of contact dermatitis were made.

Physical examination showed a well developed but poorly nourished man. Examination of the chest was not remarkable except for a high relatively fixed diaphragm. The abdomen was large and asymmetrical. There was a fluctuant, non-tender, apparently lobulated mass, which moved with respiration and extended from the fourth intercostal space on the right to two inches below the umbilicus and could be felt in both flanks, being more prominent on the right. It could not be transilluminated. There were bilateral reducible inguinal hernias and bilateral varicoceles.

The temperature, pulse and respirations were within normal limits. The blood pressure was 148 systolic, 90 diastolic.

The blood, urine and stool tests were negative except for slight anemia, a hemoglobin of 11.5 gm, and a 10 per cent eosinophilia. The nonprotein nitrogen, fasting blood sugar, amylase, cephalin flocculation, van den Bergh, and bromsulfalein test, phosphorus, alkaline phosphatase, and prothrombin time were all within normal limits. The total protein was 8 gm per 100 cc, with an albumin-globulin ratio of 0.85. An x-ray film of the chest showed nodularity of the right diaphragm. A gastrointestinal series showed a negative esophagus, a stomach displaced to the left and posteriorly, and no intrinsic involvement of the gastrointestinal tract. It was thought that the mass was related to the liver. There were a number of calcifications in the upper portion of the liver. An echinococcus skin test was positive.

On the sixth hospital day an operation was performed.

#### DIFFERENTIAL DIAGNOSIS

DR ALFRED KRANES: There are two statements in the record to which I should like to take exception. One is the description of the mass, which is said to extend from the fourth intercostal space on the right to two inches below the umbilicus. I do not see how one can feel a mass of this size in the fourth intercostal space. What is meant is that the area of liver dullness extended up to the fourth intercostal space. I find it hard to believe that the mass could be felt that high, although that is the

impression one gets from the description. One can only say that the mass extended so far below the costal margin. The other statement that I question is the description by x-ray of nodularity of the diaphragm. I think what is meant is irregularity. One cannot say that the diaphragm is nodular, can one?

DR STANLEY M. WYMAN: No.

DR KRANES: That implies a third dimension which, of course, we do not have.

DR WYMAN: The radiologist's statement in the record was, "There is irregularity of the right leaf of the diaphragm resulting from nodularity or masses projecting from the superior aspect of the liver."

DR KRANES: That makes the diagnosis easier.

DR WYMAN: The right leaf of the diaphragm is definitely elevated and as you see comes to the fourth interspace. The lung fields otherwise appear intrinsically clear. The heart shadow is prominent toward the left, probably in the region of the left ventricle. The barium-filled stomach is faintly seen in this film displaced toward the left, and the duodenal cap is displaced downward and to the left. The entire right side of the abdomen is dense and there is a suggestion of several small areas of calcification. There is a very definite mass, nodular and lobulated, on the right.

DR KRANES: As I see this problem there is no differential diagnosis. What else can this be but an echinococcus cyst? If that diagnosis is correct, and I can see no other one to make, I must say that I would not have him operated on. You must remember that he is seventy-one years old. The disease started before the age of thirty-one and although he gave a history of having felt the mass only three months before entry, you will all agree, I am sure, that an echinococcus cyst of this size must have been growing for many, many years. Furthermore, despite its size, and it does seem to be huge, it has produced absolutely no symptoms. The record states that the man was feeling quite well except for a few mild symptoms of belching and constipation. Nor has it interfered with the function of any organ although it has displaced the stomach. While it may involve a fairly large part of the liver, it has not interfered with the liver's function or produced any alteration in the laboratory tests. They were all normal. Consequently, I probably would not have advised this patient to be operated on since I see nothing to be gained by operation at seventy-one on an asymptomatic echinococcus cyst. The chances are that he might have gone another five or ten years still.

are to blame because the problem has been aggravated by their professional jealousy, indifference, over-specialization, sensitive pocketbooks and profound aversion to co-operative action." A strong indictment, indeed, but one suggesting so strong a bias as to weaken the rest of the witness's evidence.

The doctors of every town and every district society should be so organized that emergency calls, real or imaginary, are handled with reasonable dispatch. The need has been sounded by the American Medical Association and has been emphasized in these pages. Physicians cannot, however, keep themselves constantly on tap like hot and cold running water as so many of the unthinking public expect of them. Certainly, organization to meet legitimate expectations should and will be put into operation wherever possible.

So go the indictments. The doctors are accused of dodging unwelcome calls (in other words, of being human), of failing in cordiality toward those elements of the population that they know intend to cheat them, of overspecializing — specialization, according to the *Bulletin*, being both the triumph and the bane of American medicine, of indifference to chronic disease and the care of the aged, in spite of the growing interest in geriatrics and the tremendous effort being exerted for the study of cancer and heart disease, of overstressing the pocketbook, of missing its chance to improve rural care and of failing to provide adequate care to millions because of rising costs.

There is no need here of offering detailed explanations or of finding excuses. Patients who have organized their own medical affairs to the point of having reliable family doctors "whom they occasionally consult are much less likely to find themselves in urgent difficulties than those who use the profession only in an emergency, real or supposed, and then send their panic calls to the telephone operator or the police. Unfortunate incidents will occur, accidents will happen, and coronary vessels will occlude when no physician is immediately available. They are the chances that are taken in life.

In the practice of medicine as in other human activities, technic has outrun the present capacity of society to place scientific progress at the service of mankind. At this point while the spirit may be considered as willing, the social and economic flesh presents its weaknesses. A few workers of proved merit are responsible for the development of science,

human relations are dependent on the ability of entire populations to co-operate.

It is encouraging to note the interest that the *Evening Bulletin* has shown even if it is difficult to turn all its criticisms into constructive effort.

## OPERATION MUSK OX

AN analysis of the many surveys and trials of rations that were conducted on the United States and Canadian troops during the war years 1941-1946\* reveals that soldiers remained fit and healthy in temperate, desert, jungle, mountain or Arctic areas if they received plenty of beef, vegetables, white bread and butter, milk and coffee with sugar, fruit juice, pie and ice cream, candy and preserves, "provided they were able to avoid injury and disease".<sup>1</sup> It was also demonstrated that dry biscuits are not a good substitute for bread, that canned stewed meat and vegetables are not so good as roast beef and that the human being is unable to accustom himself to an insufficient supply of water.

The problem that the Army had to face was the reconciliation of these facts (the truth of which must have been suspected even before the surveys were conducted) with the obvious difficulty of providing the great American diet three times a day in every area in which bodies of troops had to be maintained if the main purposes of the war were to be accomplished. Here is indeed a poser toward the solution of which the nutritional scientists have little to offer. They are better able to describe what happens if the normal demands for food of the healthy young American adult are not met.

For example, men collapsed and were totally unfit for duty after three days during which their sole diet consisted of pemmican, tea and cigarets (a ration proposed by V. Stefansson because of its "lightness, compactness and easy preservability" — virtues that are also inherent in sawdust or baled hay). Jerked beef may have sustained Davy Crockett and Dr. Kane, but it won't do for Jack Armstrong.

On the other hand, participants in Operation Musk Ox, a Canadian army mobile exercise conducted in the Northwest Territories, from February

## THE PROVIDENCE EVENING BULLETIN LOOKS AT MEDICINE

THIRTEEN articles that appeared serially last May in the *Providence Evening Bulletin* under the ambitious title "American Medicine — Diagnosis and Prescription" have furnished a minor *cause célèbre*. This earnest effort to point out the need for reforms in medical practice cannot be dismissed lightly, for it brings to the surface certain indisputable facts. It indicates that medical service is far from perfect. It indicates the definite discontent of a considerable part of the public with the service it is receiving, and it indicates a lack of any clear understanding of the type of service

that may reasonably be expected, and how it may be obtained.

The staff reporter of the *Evening Bulletin* does not alone share with the public either its discontent or its failure to see clearly the ideal relations between physicians and their patients, and how to attain them. The very many physicians of the country — the vast majority, it may be hoped — who adhere to the ancient ideals of their profession as a calling of service share also in this discontent and in the confusion that prevails regarding the best way of improving that service.

The representative of the *Evening Bulletin* as he went his way about the country, interviewing leaders in practice, in education and in public health, in an effort to present "a synthesis of some of the best thinking that is being done on how to bring adequate medical care to the people of the United States," found more questions than could be satisfactorily answered. Many of these questions have various answers with no present indications of which are the right ones. No single group or combinations of groups of persons or even that amorphous, somewhat suspect professional conglomerate known as "organized medicine" can guarantee that its own plan is the only true one regardless of its numbers or of its expertness in vociferation.

The intention of the *Evening Bulletin* was to secure thoughtful answers to such questions as these: Is there a shortage of doctors? Is "socialized medicine" the solution for our medical problems? Is there too much specialization? Why is it hard to get a doctor in an emergency? How can the cost of medical care be reduced? What are the major trends in American Medicine? Obviously the *Bulletin* is asking questions and posing problems — by no means new ones — the answers to which the Sibylline Oracles would also like to know.

Unfortunately for the interests of a fair appraisal and the securing of thoughtful answers to these vexing problems, the *Evening Bulletin's* investigator, despite the effort that he has made to reach to the heart of the matter, shows in the presentation of his theses a regrettable failure to see both sides of the issue. In discussing the difficulty that was encountered in a number of instances in finding a doctor to answer emergency calls, no true analysis of the situations was presented, twenty doctors, on a certain Sunday afternoon were unavailable or were not immediately available, and consequently "they

The whole word method of teaching reading in the primary grades has now been in use for many school generations. It may work well for the majority,—as physicians we are not competent to judge,—but we know from experience with our own patients as well as by the increasing complaints from the secondary schools and colleges that it fails lamentably in a large minority and is apparently responsible for much of the disability in the upper grades.

The best treatment is prevention, as outlined by Koehler,<sup>2</sup> which seems to succeed with most. Failing this, we have to fall back on “remedial reading,” either individually or in small groups. Such tutoring is necessarily expensive and takes time. The wealthy can easily afford it, the middle class only at a sacrifice, and the majority not at all. Furthermore, there are not enough properly trained persons in the country to handle all the cases.

The only solution is to adapt the teaching of reading in the early grades to these children’s capabilities. As physicians and citizens we should urge this on our local school boards and teachers.

THE COSTS OF MEDICAL CARE

As has been suspected in various professional circles, the cost of living has risen more rapidly than the fees charged by physicians for medical services. This observation is noted particularly in a study, “Comparative Increases in the Costs of Medical Care and the Costs of Living” recently published by Frank G. Dickinson, Ph.D., director of the Bureau of Medical Economic Research of the American Medical Association.

The quantity of medical care has apparently increased much more rapidly than has the number of physicians practicing, the average physician, if he is keeping up with the cost of living, is doing so by increasing the load he carries rather than the rates he charges. The public that he serves is not entirely aware of this probability. It continues to grumble at all the costs of living in an extremely complicated social and economic setup.

The quantity of physicians’ services delivered in 1946 was approximately one half greater than in 1935-1939, but the number of physicians was only one seventh greater. The American people spent \$5,600,000,000 for medical care in the same year, or 3.9 per cent of its total personal-consumer expenditures. This may be compared with a 4.3 per cent expenditure in 1940.

COMMENT

Those diseases with incidence above the seven-year median are chicken pox, diphtheria, bacillary dysentery, measles, mumps, poliomyelitis, scarlet fever and typhoid fever. Those diseases with incidence below the seven-year median are German measles, lobar pneumonia and whooping cough. Diphtheria has had a higher incidence for June only once in the last twelve years, and measles only once since 1915. Bacillary dysentery is at the highest prevalence for June for the last nine years, mumps at the highest since 1915, and typhoid fever at the highest since 1945.

GEOGRAPHIC DISTRIBUTION OF CERTAIN DISEASES

Diphtheria was reported from Boston, 4, Cambridge, 2, Chelsea, 2, Chicopee, 2, Foxboro, 8, Lowell, 1, Malden, 2, Medford, 1, Melrose, 1, Needham, 1, Revere, 2, Saugus, 1, Taunton, 1, Waltham, 4, Westport, 1, total, 33.

to May, 1946, who were protected by vehicles, modern clothing and equipment against ill effects from the environment and were supplied by air at all times, with a wide variety of fresh food and packaged rations, experienced none of the classic diseases and hazards of Arctic travel such as exposure, frostbite, snow blindness, psychosis, exhaustion, starvation, scurvy, edema and cold nephritis, although many of them were troubled by symptoms of carbon monoxide poisoning as a result of inhaling exhaust gases blown back into their vehicles by a strong following wind near Baker Lake, and one obese (225-pound) person lost 29 pounds between Churchill and Fort Nelson, where when seen he was in excellent health.

In desert areas, an example of misguided planning was the lining of canvas Lyster bags with a plastic to prevent evaporation. This resulted in warm water with a queer taste. By contrast, the traditional evaporating canvas desert bag produced cool, palatable water, and little was wasted. It was also learned that teaching soldiers to salt their food heavily in hot climates is preferable to giving them uncoated salt tablets, which may nauseate them.

United States troops, it is reported, will never force themselves to eat for long periods items that they dislike, even though they go hungry. This is illustrated by the tendency of the American soldier to throw away the dog biscuits in his C ration. The fact that these packages were usually at least twelve months old before they reached the consumer probably explains his reaction.

Napoleon is credited with the statement that an army marches on its stomach, and Grant with the remark that beans killed more of his soldiers than bullets. The results of these contemporary studies indicate that one must still take to heart the observations of such veteran campaigners.

## TEACHER AND DOCTOR AGREE

Nor infrequently articles of great interest to physicians turn up in the publications of other professions, where they usually escape the doctors' notice. A recent example is the appearance of two articles on specific reading disability in the current April and May issues of the *Independent School Bulletin*. One is by a member of the staff of the Language Clinic of the Massachusetts General Hospital,<sup>1</sup> and the other by a teacher at Milton

Academy.<sup>2</sup> They are prefaced by a brief editorial note giving them the enthusiastic commendation of the principals of five well known secondary schools. The information contained in them deserves wider publicity.

The two papers are written in nontechnical language suitable for intelligent parents as well as for teachers and physicians. The first summarizes what physicians have learned about specific reading disability, and the second what an alert school can do to prevent the disastrous consequences that frequently result from failure to recognize or improper handling of children with the disability.

The authors agree that specific disability in the use of language, particularly reading, afflicts between 10 and 15 per cent of intelligent children and that, unless recognized early and handled properly, it results in scholastic failure, in a variety of behavior problems and eventually, in some cases in misplaced and maladjusted adults. In all but the smallest communities one tenth of the pupils means a good many children, and the number for the country as a whole must run close to two and a half million.

The subject is one with which all physicians dealing with children should be familiar. Unrecognized cases are taken to ophthalmologists because teachers and parents believe that there must be something wrong with the children's eyes, to general practitioners and to pediatricians because there must be something wrong with their general health or their "glands," and to neurologists and psychiatrists because the children seem stupid or inattentive or simply mischievous at school, whereas the real trouble is in the way the victims' brains are organized. Their intelligence is normal or often superior, but their visual memory for language is so slow and faulty that they are unable to learn to read by the currently popular whole-word method. That their failure is not due to lack of attention on their part or to emotional blocking is shown by the fact that they can and do learn when they are taught phonetically with auditory and kinesthetic re-enforcement.

Koehler<sup>2</sup> brings out in his article that there are only ninety-four letters and letter combinations for the child taught in this way to memorize, which is a much lighter load on the visual language memory than the many hundreds of individual words that the average third grade pupil is supposed to be able to recognize by sight.

by Joe Marsh

## It's Leap Year, Girls!

*First girl in our town to "get her man" on Leap Year was the Smiths' daughter, Tiny, who wed Bill Webster's boy last Saturday*

When I asked Bill Jr. if it was true that Tiny really did the proposing, Bill said No, but she made it mighty plain that she'd make an ideal wife. Instead of looking for diversion or excitement every evening, she was content to chat beside the fire

*"I could plainly see," says Bill, "that we'd really have a happy home life—which is just exactly what I want from marriage"*

I know it's customary for older folks to shake their heads over the younger generation (It's gone on now for hundreds of years)

*But from where I sit, young people of marrying age today are every bit as commendable as their elders were—in their temperance (a glass of beer for instance), tolerance, and common sense. So to Tiny and Bill—the best of luck!*

Joe Marsh

Dysentery, bacillary, was reported from Worcester, 27, total, 27

Encephalitis, infectious, was reported from Lowell, 1, Lynn, 1, Millbury, 1, Quincy, 1, Saugus, 1, total, 5

Lymphocytic choriomeningitis was reported from Waltham, 1, total, 1

Meningitis, meningococcal, was reported from Boston, 1, Cambridge, 1, Fall River, 2, total, 4

Meningitis, Pfeiffer-bacillus, was reported from Cambridge, 1, Hatfield, 1, Holyoke, 1, Lynn, 2, Winchester, 1, total, 6

Meningitis, other forms, was reported from Middleboro, 1, Somerville, 1, Worcester, 1, total, 3

Meningitis, mumps, was reported from Walpole, 1, total, 1

Meningitis, undetermined, was reported from Cambridge, 3, North Adams, 1, Randolph, 1, Springfield, 1, Waltham, 2, Westwood, 1, total, 9

Polymyelitis was reported from Dover, 1, Gloucester, 1, Melrose, 1, total, 3

Awarded the Nobel Prize in Medicine and Physiology in 1934 with Dr William P Murphy, of Boston, and Dr George H Whipple, of Rochester, New York, for discoveries in the treatment of anemias, Dr Minot has devoted over thirty years to medical research teaching and has made important contributions to the subjects of anemia, abnormal bleeding and the treatment of leukemia by x-ray

Dr Castle has received honorary degrees from Yale University and from the University of Utrecht, Holland. He is also the recipient of the John Phillips Memorial Award of the American College of Physicians, the William Procter, Jr., International Award for Distinguished Service in Promoting Health, and the Walter Reed Medal of the American Society of Tropical Medicine

## ODONTOLOGIC CHARACTERISTICS OF LONG-TAILED PRIMATES

New World monkeys, according to Sir Frank Colyer, (*Brit M J* 1 1202, 1948) differ from Old World monkeys in various anatomic particulars, especially various odontologic characteristics. The green monkeys of St. Kitts, however, exhibit the greatest capacity for dental variations. The incidence of supernumerary teeth, abnormal positions, rotations and inward displacements is three or four times as great in this species as in comparable groups of African monkeys

## STUDENTS OF ADMINISTRATION PLACED

At the completion of the first year of Yale University's course in hospital administration, 8 students found immediate placement. Of these, 1 remained at the Grace-New Haven Community Hospital, 5 found positions in Boston, 1 accepted an administrative internship in Rochester, N Y, and 1 will fill a similar position in Valhalla, N Y

## MISCELLANY

### ASSOCIATION OF SCHOOLS OF PUBLIC HEALTH

Brigadier General James S Simmons (Retired), dean of Harvard School of Public Health, was recently elected president of the Association of Schools of Public Health at the annual meeting of the Association

### JAMES D BRUCE MEMORIAL LECTURE AND MEDAL

The James D Bruce Memorial Lecture in Preventive Medicine was recently delivered by Brigadier General James S Simmons (Retired), dean of Harvard School of Public Health, at the annual convocation of the American College of Physicians in San Francisco. His subject was "The Challenge of Preventive Medicine"

General Simmons was awarded the James D Bruce Memorial Medal for achievement in preventive medicine

### CAT-OF-NINE-TAILS DEBARRED

England's House of Lords, according to the *British Medical Journal* (June 12, 1948), debated two days and deleted the clause inserted in the Criminal Justice Bill by the House of Commons for the suspension of the death penalty for murder. Flogging was retained as a penalty, but the use of the cat-of-nine-tails was debarred

### DIRECTOR OF THORNDIKE MEMORIAL LABORATORY

Dr William B Castle, professor of medicine at the Harvard Medical School, has been named to succeed Dr George R. Minot as director of the Thorndike Memorial Laboratory of the Boston City Hospital, where he has been associate director since 1932

With Dr Castle's appointment, Dr Minot, Nobel Prize winner in 1934, retires from his joint positions as professor of medicine at the Harvard Medical School and director of the Thorndike Memorial Laboratory

## CORRESPONDENCE

### IN CORPORE SANO

To the Editor: Congratulations to Professor Koon on his article in the *Boston Traveler* on June 11, 1948. The last paragraph says, "Bark beetles which carry the fungus of the Dutch elm disease will not breed in healthy living tree tissue. Keep your elms healthy by feeding them."

The organic gardeners have proved for years that healthy plants are practically free from diseases and bugs. Many people, including some doctors, are of the belief that a good part of the increase of cancer is due to poor food. Much of this poor food is due to an excessive use of commercial fertilizers. The organic method, with no commercial fertilizers, dusts or sprays and plenty of humus in the soil, produces vegetables that make healthier people and less sickness. The organic gardeners are called zealots or fad dists by some. It is the opinion of many that those opposed to organic gardening are either jealous or are connected in some way with the all-powerful chemical companies. We would not go back to the old chemical method if the chemical companies offered us a life pension!

## It's Leap Year, Girls!

*First girl in our town to "get her man" on Leap Year was the Smiths' daughter, Tiny, who wed Bill Webster's boy last Saturday.*

When I asked Bill Jr if it was true that Tiny really did the proposing, Bill said No, but she made it mighty plain that she'd make an ideal wife. Instead of looking for diversion or excitement every evening, she was content to chat beside the fire

*"I could plainly see," says Bill, "that we'd really have a happy home life—which is just exactly what I want from marriage"*

I know it's customary for older folks to shake their heads over the younger generation (It's gone on now for hundreds of years)

*But from where I sit, young people of marrying age today are every bit as commendable as their elders were—in their temperance (a glass of beer for instance), tolerance, and common sense. So to Tiny and Bill—the best of luck!*

Joe Marsh

## TRAUMATIC NECROSIS OF PRETIBIAL MUSCLES\*

CARL PEARSON, M.D.,† RAYMOND D. ADAMS, M.D.,‡ AND D. DENNY-BROWN, M.D.§

BOSTON

**A**N UNUSUAL case in which the pretibial muscles of both legs became acutely swollen, painful and paralyzed after a period of vigorous activity was recently observed on one of the medical wards of the Boston City Hospital. The clinical features were puzzling, and it was only after a biopsy had disclosed hemorrhage and necrosis that a clue to the nature of this disorder was obtained. Since we were unfamiliar with this condition and are unable to find verification of exactly similar cases in the medical literature, the following case is reported.

### CASE REPORT

**S T**, a 24-year-old man, who had emigrated from Greece less than a year before, could not express himself well in English, and the history was therefore obtained through an interpreter.

It was learned that his general health had always been good. His only important illness in the past had been malaria 2 years before entry, which had been treated by intramuscular injections of an unknown medicine. The only other item of possible interest was an easy fatigability of the legs, which had been present for the past year. The patient denied the ingestion of pork. Ten days before admission to the hospital he had had a sore throat and hoarseness from which he had recovered within 24 to 48 hours without interruption of his work as a bus boy.

At about 2 p.m. on May 19, 1947, he had competed with two companions in broad jumping on a cement pavement. Later during the same evening he began to experience sharp pains in both legs, and there was tenderness of the muscles from knees to ankles. He felt feverish, had general malaise and, after a restless night, was admitted to the hospital.

Physical examination disclosed a patient whose face was flushed and who was suffering considerable pain. He was alert and co-operative. Oral hygiene was poor, and one tonsil was enlarged and red. There was a Grade I apical systolic murmur. The heart and lungs were not remarkable. The liver and spleen could not be palpated. The patient lay with his legs flexed at hips and knees. The skin over the anterior surface of both legs from knees to ankles was pink and distinctly warmer than elsewhere. We examined the patient at this time and noted that all the muscles in

the anterior tibial compartment were very firm and exceedingly tender. There was foot drop bilaterally and complete paralysis of the anterior tibial, extensor digitorum longus and extensor hallucis longus muscles. Passive flexion or extension of the feet at the ankles was painful. The peroneal, gastrocnemius and other muscles in the legs and thighs contracted normally and were not tender. The joints were neither swollen nor tender, and no thrombosed veins could be felt. There was slight hyperalgesia over the erythematous skin surface. The knee and ankle jerks were present, and the plantar reflexes were flexor bilaterally. Vibratory and

FIGURE 1 Right Anterior Tibial Muscle Seventeen Days after Injury ( $\times 50$ )

*Regenerating muscle fibers and remnants of necrotic muscle are widely separated by proliferating fibrous connective tissue, in which lymphocytes, plasma cells and macrophages are seen.*

position senses in the feet were normal. Pulsations were felt in the dorsalis pedis and posterior tibial arteries.

The temperature was 100.8°F, the pulse 84, and the respirations 22. The blood pressure was 128/88.

At the time of entry the urine was normal, but on the 3rd and 5th hospital days it gave +++ and ++ tests for albumin respectively. The white-cell count was initially 10,800, with 85 per cent neutrophils, 14 per cent lymphocytes and 4 per cent monocytes. Subsequently it was 8050, with a normal differential, except on the 6th hospital day, when there was an eosinophil count of 4 per cent. The hemoglobin was 14 gm per 100 cc. The nonprotein nitrogen and fasting blood sugar were within normal limits. The stool was negative for blood and parasites. The blood Wassermann, Hinton and gonococcus complement-fixation tests were all negative. The skin test with trichina antigen gave no reaction. The concentrations of creatine and creatinine in the blood and urine were normal. The cerebrospinal fluid was examined twice, each time being entirely within normal

limits. X-ray films of the chest and legs disclosed no abnormalities. Watson's test for porphyrins in the urine was negative. An electrocardiogram was normal.

On the 3rd hospital day the temperature rose to 102.4°F, and the patient appeared quite uncomfortable. Penicillin

Some of the pieces contained apparently normal muscle fibers, whereas in others the normal skeletal muscle architecture was severely disrupted and there was a marked fibrous tissue replacement (Fig 1 and 2). In these areas, muscle fibers were observed in all stages of degeneration. Some were swollen, intensely acidophilic and devoid of nuclei and striations, others were granular and vacuolated,

FIGURE 2 Cross-Section from the Area Demonstrated in the Upper Part of Figure 1, showing the Rounded Contours, Occasional Vacuolization and Hyperplasia of Muscle Nuclei in the Remaining Fibers ( $\times 200$ )

was then given intramuscularly in doses of 25,000 units every 3 hours. The temperature gradually subsided over a period of 4 days. The leg muscles remained hard and indurated but were less tender, and the pretibial erythema gradually faded. By the 14th hospital day the patient was feeling quite well though foot drop and paralysis of the extensor muscles of the feet and toes continued. Tests of the electrical excitability of these muscles showed no reaction to either faradic or galvanic stimulus. On the 17th hospital day a biopsy of the upper part of the anterior tibial muscle of the right leg was performed. From this a diagnosis of traumatic myopathy was made. Improvement in the patient's general condition continued, but when he was dis-

FIGURE 4 Longitudinal Section of a Part of the Muscle that is Undergoing Regeneration ( $\times 200$ )

There are rows of muscle nuclei in the fibers. The fiber in the right upper corner has acquired transverse and longitudinal striations. The fibroblasts and interstitial cellular reaction consisting of macrophages, lymphocytes and plasma cells are demonstrated.

and their nuclei were shrunken and pyknotic. In two places the general architecture of a fasciculus could be distinguished. In these the central portion of each fasciculus was necrotic, consisting of swollen eosinophilic fibers with frequent transverse fissures and shrunken pyknotic nuclear remnants.

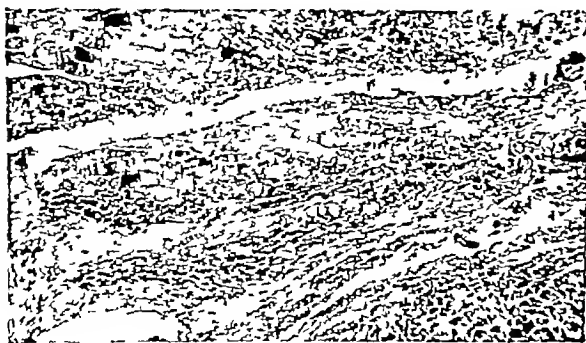

FIGURE 3 Longitudinal Section of Muscle ( $\times 50$ )

The fibers in the center of the field, which are necrotic, are stained a bright red, are homogeneous and lacking in either transverse or longitudinal striations and are cracked transversely. In the lower margin active phagocytosis of the degenerated muscle fibers is demonstrated.

charged after 27 days in the hospital, the anterior tibial muscles were still paralyzed.

Several small pieces of the right anterior tibial muscle were excised, fixed in Zenker's solution and stained with phloxine and methylene blue, and phosphotungstic acid hematoxylin.

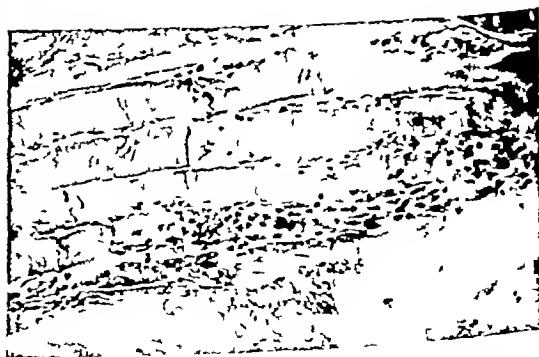

FIGURE 5 Higher Magnification of the Lower Part of the Field Demonstrated in Figure 3, Showing the Necrotic Muscle Fibers and Their Removal by Macrophages ( $\times 200$ )

(Fig 3) The connective tissue appeared to be inactive. At the borders of each fasciculus extensive regenerative activity was evident (Fig 4). The muscle fibers in this region were small, and contained large numbers of well stained muscle nuclei. Longitudinal splitting was commonly observed, and the sarcoplasm had a well developed longitudinal striation. In one fasciculus hemorrhage had separated both necrotic and regenerating fibers. Some fibers were invaded and surrounded by macrophages and hemorrhage. (Fig 5) All that remained of many muscle fibers were the sarcolemmal sheaths. Many of these were partially collapsed and contained granular clumps of acidophilic material, some of which was present in macrophages (Fig 6).

The interstitial fibrous connective tissue was increased in amount and was present in the form of broad bands and slender strands, which separated the remaining muscle fibers. The connective tissue was cellular, fibroblast nuclei were increased in number and size. In addition, there were many macrophages, somewhat fewer lymphocytes, a few plasma cells and an occasional neutrophil. Large numbers of well preserved red cells were widely dispersed throughout the damaged parts of the muscle, and many macrophages contained yellow-brown granules of pigment, presumably hemosiderin (Fig 7). The walls of the small arteries were thickened, and their endothelial cells were unusually large and numerous.

No less striking were the evidences of changes usually interpreted as regeneration of muscle fibers (Fig 4). In many fibers there was a marked proliferation of the muscle nuclei. Closely packed clusters or rows of nuclei were seen, either just beneath the sarcolemma or in the center of the fiber. As many as fifty could be counted in a short segment of a fiber. Narrow, elongated buds of muscle protoplasm extended out from the muscle fibers exhibiting this nuclear hyperplasia. Some of the thin regenerating fibers were arranged parallel to one another, and others were not oriented in any particular plane. There were well developed transverse and longitudinal striations in some of these fibers.

When the patient was last examined, 5 months after the onset of the illness, bilateral foot drop was still present, and

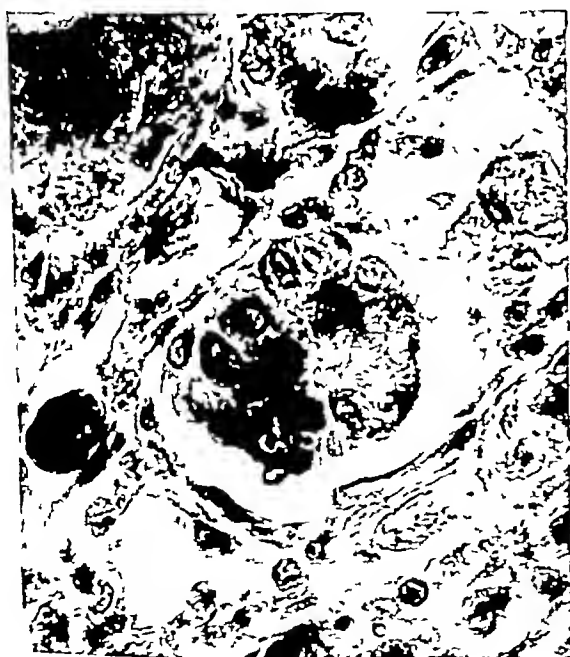

FIGURE 6 Cross-Section of a Necrotic Muscle Fiber the Remnants of Which are Surrounded by Phagocytic Cells (x 800)

there was moderate atrophy but no tenderness of the anterior tibial muscles. An electromyogram was done by one of us (D D-B) at that time. No evidence of electrical activity could be obtained from any part of the tibialis anticus muscle on either side. The natural rhythms of motor activity were present in the peroneal group of muscles on both sides. The tibialis anticus muscle felt unusually firm but was no longer swollen or tender. Passive plantar flexion of the ankle was limited owing to fibrous resistance in the tibialis anticus muscle. Plantar flexion of the great toe on both sides was limited slightly by a similar contracture.

DISCUSSION

The pain, tenderness, firm swelling and paralysis of the pretibial muscles that constituted the chief symptoms were indicative of a primary disorder of muscles. The absence of reflex changes and sensory loss and the lack of electrical excitability

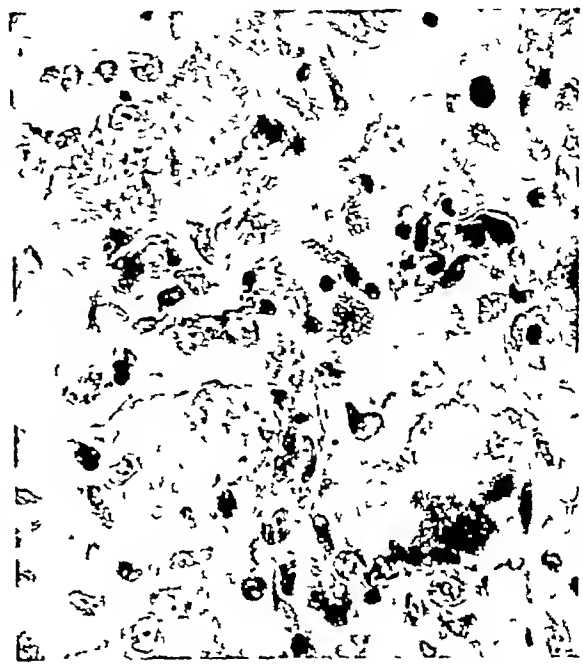

FIGURE 7 Hemosiderin in Macrophages Appearing as Refractile Granules and Lymphocytes, with the Plasma Cells and Macrophages between Multinucleated Muscle Fibers (x 800)

of the involved muscles tended to exclude the possibility of disease of the peripheral nerves. The erythema and warmth of the skin were believed to signify an acute inflammatory reaction in the underlying muscles,—an acute myositis,—and the fever, malaise and albuminuria were regarded as systemic manifestations.

There was at first much uncertainty about the type of muscular disease with which we were dealing. Polymyositis, dermatomyositis, trichinosis and acute suppurative myositis were all considered but seemed unlikely because of the acute onset after strenuous exertion, the lack of definite skin lesions and the restriction of the process to the pretibial muscles. Other diseases considered in the differential diagnosis were erythema nodosum, diffuse vascular diseases, such as disseminated lupus erythematosus and periarteritis nodosa, and pretibial fever. Erythema nodosum was ruled out by the absence of definite skin nodules and by the occurrence of pronounced muscle swelling and paralysis, to which we could find no reference in

medical writings. Diffuse vascular diseases could not be established since most of the cardinal criteria of these diseases were lacking. Pretibial fever, in which the leading clinical manifestations have recently been described by Daniels and Grennan,<sup>1</sup> was suggested by the location of the pain, the fever and the systemic symptoms. However, the case reported above deviated widely from published accounts of this disease, in which fever, splenomegaly and skin eruption were prominent features and muscle paralysis did not occur.

The muscle biopsy, though giving only a fragmentary picture of the pathology, was of considerable help in ascertaining the possible causes of this clinical condition. The extensive necrosis of muscle fibers, the hemorrhage, the proliferation of fibrous connective tissue and the muscle regeneration indicated an acute destructive process that was subsiding. The lymphocytes, the occasional neutrophils and eosinophils and the plasma cells were believed to be a reaction of tissue necrosis. These findings corresponded approximately to the microscopical changes described in human beings by Lorenz<sup>2</sup> and others and by Clark<sup>3</sup> in animals several days after experimental crushing of muscle tissue. The histopathology in this case differed from that reported in bacterial and parasitic infections of muscle and from the less well defined dermatomyositis or polymyositis.

The origin of the muscle necrosis could not be established with certainty. Since strenuous exertion—namely, broad jumping on a cement pavement—had initiated the illness, trauma was considered an important factor. Indeed the occurrence of muscle necrosis due to trauma is not without precedent in the medical literature. There is in fact an extensive literature on this subject, which is well summarized by Lorenz<sup>2</sup> and by von Myenburg et al.<sup>4</sup>

However, we have been able to find only 2 cases similar to the one reported above. One was included among a series of cases discussed by Sirbu, Murphy and White.<sup>5</sup> Their patient was a thirty-eight-year-old Filipino soldier who developed severe pain over the anterior aspect of both lower legs after a prolonged march. The anterior tibial muscles of both legs were swollen and tender and at operation bulged through the incised fascia as gray-white masses. Upon release of pressure by removal of a portion of the crural fascia the right leg recovered fairly well, but the muscles of the left were almost completely gangrenous and had to be excised. The subsequent course of this illness is not given. The authors suspected a vascular lesion because of the extent of the necrosis.

The other case was recently presented by Phalen,<sup>6</sup> who reported 4 cases of ischemic necrosis of the anterior crural muscles incident to trauma. Three of his cases were quite different from ours in that a fracture of the tibia and fibula had been at-

tended by necrosis of the pretibial muscles. But in the other case painful swelling and paralysis of the pretibial muscles of one leg had occurred in a young man who had walked a half mile. At operation the muscle tissue was found to be soft, friable and reddish gray. Injury or functional occlusion of the anterior tibial artery was offered as an explanation for the muscle paralysis.

The possible relation of this condition to the mild and relatively common affliction of muscles known as "shin splints" and to traumatic myalgia is interesting. Every athletic coach is well acquainted with the tenderness and pain in the pretibial muscles that occurs when runners, broad jumpers and hikers begin to train. The affected muscles become firm and swollen, and any attempt at active or passive flexion and extension at the ankle is painful. The cause is assumed to be recurrent trauma of the unconditioned muscles, nothing is known of the pathology. Rest and warm applications may be required in severe cases, but most athletes "walk off" their ailment. We have been unable to find any record of paralysis and subsequent atrophy of muscles, and Dr. Christoff\* here knew of none. Trauma, which produces acute and chronic myalgia, is also quite common, but again no adequate pathological studies are available and it seems unlikely that it would be attended by complete paralysis.

Rupture of muscles after violent exertion is also well known, occurring not infrequently as an occupational disease. This subject is reviewed in detail by Lorenz.<sup>2</sup> Gilcreest,<sup>7</sup> who has discussed the subject at length, has observed rupture of the neck muscles in loaders and packers, of the biceps and triceps in baseball pitchers and weight lifters, of the adductors of the thigh in horseback riders and of the rectus abdominis in an Indian broad jumper. The usual sequence of events is a violent contraction of a muscle group when the antagonists are suddenly brought into action, a snap, severe pain, swelling and local bulge in the muscle. The rupture, which may become complete only after twenty-four hours, is usually in the belly of the muscle and although the muscle is weakened, paralysis does not occur unless all the tendinous attachments are torn. It is unlikely that muscle rupture can be held responsible for the firm swelling, paralysis, erythema of the skin and fever that occurred in the case reported above.

The only satisfactory explanation of the pathogenesis of this syndrome that we are able to suggest is that violent contraction led to rupture of muscle fibers and possibly to hemorrhage. The affected pretibial muscles, contained as they are in a fairly rigid compartment formed by the tibia, fibula, interosseous membrane and crural fascia were further damaged by the ischemia incident

\*Director, Department of Student Health, Boston University (personal communication).

to edema and hemorrhage. We were unable to obtain evidence, either clinical or pathological, of injury to the anterior tibial artery as proposed by Sirbu and his co-workers<sup>5</sup> and Phalen.<sup>6</sup> However, more complete pathological studies are necessary to settle this point. The possibility that influenza or respiratory infection had predisposed the muscles to trauma can neither be affirmed nor denied though the lack of distinct symptoms preceding the trauma makes this unlikely.

SUMMARY

A case of a young man who developed severe pain, swelling and erythema of the anterior aspects of both legs after broad jumping on a cement pavement is presented. This was followed by paralysis of the pretibial muscles, which subsequently underwent atrophy. A muscle biopsy, performed seventeen days later, revealed extensive destruction of

muscle tissue and hemorrhage and slight regenerative activity of some muscle fibers. Trauma was believed to be the main etiologic factor.

NODULAR GOITER AND THYROID CANCER

THOMAS J ANGLEM, M D,\* AND MARTIN L BRADFORD, M D†

BROOKLINE, MASSACHUSETTS

IN THE therapeutic attack on malignant tumors in general, the accumulated experience of generations has established as virtually axiomatic certain well defined principles.

The first is the folly of attempting to arrive at a diagnosis by observation of the continued growth of a tumor or area of nodularity until its malignant nature is clear and unmistakable. As stated by Taylor,<sup>1</sup> one must answer the question, "What is the disease?" It must be answered early, by biopsy or by removal of the lesion in question.

A second is the great utility of the principle of prophylactic removal of lesions that, though apparently benign, are known to be at times actually malignant or to be capable of malignant degeneration. This principle is almost universally accepted in the therapy of such conditions as leukoplakia of the oral cavity, keratosis of the skin, papillomas of the bladder, polyps of the rectum and colon and kraurosis vulvae.

On the basis of this fundamental attitude, supported by an impressive array of statistical evidence indicating a high incidence of cancer in the nontoxic nodular goiter, most surgeons who have concerned themselves with the subject have favored removal of such growths. The incidence of cancer in nontoxic nodular goiter, as reported from representative surgical clinics in different parts of the country,

varies from 4.8 to 11.0 per cent (Table 1). All reporting clinics have shown a higher incidence in single adenoma than in the multinodular nontoxic

TABLE 1 Incidence of Cancer in Nontoxic Adenomatous Goiters

phylactic thyroidectomy for nodular goiter, even though it may be symptomless.

It is recognized that the incidence of cancer in simple diffuse goiter, in primary hyperplasia and

\*Assistant professor of surgery, Boston University School of Medicine, visiting surgeon, Massachusetts Memorial Hospitals and New England Baptist Hospital.

†Assistant in surgery, Boston University School of Medicine, second assistant visiting surgeon, Massachusetts Memorial Hospitals.

in toxic adenomatous goiters is so low as to be of no significance in the general problem. It is also recognized that certain adenomatous goiters require thyroidectomy because of toxicity or because of substernal, retrotracheal or intrathoracic extension productive of serious pressure symptoms. The operation in these cases can in no sense be considered a prophylactic procedure.

The crux of this problem thus revolves about the attitude that should be taken toward the single adenoma and the relatively symptomless and usually small or moderate-sized multinodular nontoxic goiter. The validity of the principle of prophylactic thyroidectomy in such cases has recently been questioned by Rogers, Asper and Williams,<sup>6</sup> who

support their point of view by data obtained from the study of the records of 3221 cases drawn from all services of the Boston City Hospital, the Johns Hopkins Hospital and the Massachusetts General Hospital.

In support of their point of view, Rogers, Asper and Williams lay great emphasis on an alleged discrepancy between the incidence of thyroid cancer in surgical specimens and that in "clinical" and autopsy material, the significance of the factor of variability is the degree of malignancy in thyroid cancer and in the morbidity and mortality associated with thyroidectomy. VanderLaan<sup>7</sup> also stresses the low incidence of thyroid cancer in autopsy material and implies on the strength of this that surgical pathologists are diagnosing as thyroid cancer lesions that are not malignant.

Since nodular goiter is not uncommon, it is highly desirable to arrive at some measure of accord regarding the therapy, if any, that should be recommended to the patient with an otherwise symptomless unimodular or multinodular goiter.

A challenge such as that implied in the paper of Rogers, Asper and Williams serves a useful purpose in compelling a reappraisal of prevailing attitudes and critical re-examination of the bases on which they rest.

With these considerations in mind, we have undertaken a critical and objective review of the data on which the two conflicting points of view rest

and have, in addition, made a study of the records of 1377 patients from the Thyroid Service at the Massachusetts Memorial Hospitals and from our office. All patients having had thyroidectomy or excision of thyroid nodules are included. Patients having had two-stage operations are counted only once. Among the 1377 patients, cancer was encountered in 46 cases, or 3.3 per cent. The incidence of cancer among the various types of goiter is indicated in Table 3.

The types of cancer encountered were as follows: papillary adenocarcinoma (18 cases), adenocarcinoma (11 cases), small-cell carcinoma (5 cases), giant-cell carcinoma (4 cases), Hürthle-cell carcinoma (2 cases), embryonal-cell carcinoma (2 cases), fetal adenoma with blood-vessel invasion (2 cases), fibrosarcoma (1 case), and hemangiosarcoma (1 case). Only 2 cases fell in the borderline group of so-called fetal adenoma with blood-vessel invasion, and in 1 of these the malignant character of the lesion was subsequently confirmed by the development of a metastasis.

Our findings regarding the incidence of cancer fully confirm reports from other surgical clinics in nonendemic areas.

It is our belief that the alleged discrepancy between the incidence of cancer in surgical statistics and that found in "clinical" material does not, in fact, exist. Rogers, Asper and Williams,<sup>6</sup> for example, report an incidence of 1.99 per cent of all patients with goiter, but the total figure on which this calculation is based includes 907 toxic diffuse goiters, 400 nontoxic diffuse goiters, and 377 toxic nodular goiters, all of which play little or no part in this problem. Only 5 of the 74 cases of cancer reported occurred in the toxic group. It is possible from the figures supplied by Rogers, Asper and Williams to calculate the incidence of cancer in the nontoxic nodular group, which, for their entire series, is 4.79 per cent and, for the material that they report from the Johns Hopkins Hospital, 11.2 per cent.

Both VanderLaan<sup>7</sup> and Rogers et al.<sup>6</sup> attach great significance to the infrequency with which carcinoma of the thyroid gland is found as the cause of death in autopsy studies. Jaffé's<sup>8</sup> report of a ratio of 2:1000 is cited by VanderLaan. A ratio of less than 1:1000 in 11,000 autopsies was found at the Massachusetts General Hospital, an incidence of 5 cases in more than 6000 autopsies at the Peter Bent Brigham Hospital, and an incidence of 5 cases in 18,668 cases from the Boston City Hospital. The last figure is so far out of line with the others reported that its accuracy must be questioned.

We believe that this is fallacious reasoning and that the apparent discrepancy is due to the fact that in fatal cases of thyroid cancer the patient has usually had the disease for a long time before the terminal stage is reached and that, except for an

occasional patient who is rushed into the hospital in acute dyspnea and for the rare operative mortality, these patients usually die at home

In a study of 1657 autopsy records from the Department of Pathology of the Massachusetts Memorial Hospitals for the thirteen-year period from January, 1934 to September, 1947, we found confirmation of the low incidence of cancer as a cause of death in this type of material. Thyroid cancer was not found to be the cause of death in a single case (657 of these records were on children under the age of ten years). However, neither did we find a single case of cancer of the tongue, floor of the mouth, gingiva, buccal mucosa, or palate, which as a group are considerably more common than thyroid cancer. We also found that our figures suggested that cancer of the duodenum was half as common as cancer of the cervix, — a patent absurdity.

The significant fact we believe to be this in a period shorter by two years than that covered by the autopsy survey we found 11 patients (from the Massachusetts Memorial Hospitals and from a single private office) who are known to be dead of thyroid cancer. Only 1 of these came to autopsy, and that one at another hospital. It is important to point out that none of the private cases of the remainder of the entire hospital staff are included, and yet their contribution to the autopsy material is included. If a similar situation prevails in other medical centers, and we see no reason to doubt that it does, the actual incidence of death from thyroid cancer is more than ten times greater than autopsy statistics suggest.

Rogers, Asper and Williams<sup>6</sup> emphasize the point that a large percentage of thyroid cancers fall in the group of low or moderate malignancy and suggest that because of this fact a conservative attitude is warranted and that one may wait in dealing with such patients until there is definite objective evidence that cancer is actually present, such as a recent sudden increase in the size of a nodule or the appearance of an increased hardness in the consistency of such a nodule. Against this teaching, it is only necessary to report such end results as those of Ward,<sup>3</sup> who found that when carcinoma of the thyroid gland was diagnosed or suspected on clinical examination, 80 per cent of patients were dead at the end of five years, that when carcinoma was diagnosed at operation, 60 per cent were dead after five years and that when the diagnosis was first made at pathological examination only 20 per cent were dead, it may be pertinent to point out that Cochrane,<sup>9</sup> reporting from the Boston City Hospital on 559 thyroidectomies done between 1925 and 1937, found not a single case of cancer of the thyroid gland diagnosed clinically that was surgically operable.

The mortality and morbidity associated with thyroidectomy is put forward by Rogers, Asper and

Williams<sup>6</sup> as a potent argument against prophylactic thyroidectomy. They cite a 15.3 per cent incidence of complications and 5 fatal cases in a series of 431 patients who had thyroidectomies for nontoxic goiter, diffuse or nodular. At least 4 of the operations in the fatal group could by no stretch of the imagination be called "prophylactic."

It is not at all unreasonable to suggest that prophylactic operations performed five, ten, fifteen or twenty years earlier might have obviated these fatal outcomes as well as many of the graver complications. The 15.3 per cent incidence of complications cited is not the incidence of complications that follow thyroidectomy done as a prophylactic procedure, but for the entire group, which unquestionably contained many complicated surgical problems.

It is well known that in the hands of competent thyroid surgeons the incidence of mortality and serious complications is almost wholly limited to the complicated case — the large goiters with retrotracheal, substernal or intrathoracic extension. To cite such complications as an argument against prophylactic removal of discrete adenomas or small nodular goiters is simply to confuse the issue. Lahey<sup>10</sup> has stated

The mortality of removal, particularly in the type of adenoma that is likely to become malignant, ought to be zero because it is a discrete adenoma and easily removed. These patients are in the hospital not over a week, so why trade the hazards of malignancy in a thyroid adenoma of this type when there is no risk and the hospital stay is so short?

With this we concur.

In our own series of nontoxic nodular goiters we have excluded all cases in which there was a clear-cut complaint of pressure symptoms, all patients who had substernal, retrotracheal or intrathoracic extension, and all whose goiters were estimated to be 7 cm in diameter or larger. The remaining group of 331 cases consisted of 220 single adenomas and 111 small or moderate-sized, essentially symptomless multinodular nontoxic goiters. We believe that the term "prophylactic thyroidectomy" can be applied only to this group. Actually, many of these patients wished to be rid of their goiters and the number of cases in which the operation was truly prophylactic was much smaller than the figure given. There were no deaths. The complications occurring in this entire group consisted of 1 case of deep thrombophlebitis, 2 cases of hypothyroidism, 2 cases of keloidal scars, and 12 cases of serum in the wound, all of which cleared up uneventfully in one month or less.

#### CONCLUSIONS

The high incidence of cancer in single thyroid adenomas from our own study (9.0 per cent) makes obligatory the removal of all single thyroid nodules.

The incidence of cancer in nontoxic multinodular goiters (4.8 per cent) is sufficiently low so that

we concede that the propriety of operating on all such patients might be questioned if there were not other compelling reasons why the growths should be removed. It is our opinion that the multinodular goiter is not a simple benign process, but a progressive disease that goes on, first to develop toxicity in a significant percentage of cases, as indicated by the increasing incidence of toxicity as one ascends the age scale,<sup>11</sup> and secondly, to produce serious mechanical disturbance, chiefly by compression and deviation of the trachea by retrotracheal, substernal and intrathoracic extension. The frequency of such manifestations is indicated by Means's<sup>11</sup> report of an incidence of pressure symptoms in 65 per cent of cases of nontoxic nodular goiter at the Massachusetts General Hospital.

The mortality from operations that can be classed as prophylactic is virtually zero.

The incidence of complications in operations on this class of patient is insignificant, compared with the hazards of leaving the goiter

## PENICILLIN IN THE TREATMENT OF DIPHTHERIA AND THE DIPHTHERIA CARRIER STATE

JOHN D CRAWFORD, M D \*

BOSTON

THE importance of diphtheria has been re-emphasized lately by experiences with the disease in foreign countries during the war and its aftermath and by slight but statistically significant increases in the prevalence of diphtheria in this country. The clinical manifestations and complications have been completely described in the older literature. An important aspect of the problem now being developed is the application of antibiotics in treatment. The value of penicillin in diphtheria has been established in extensive clinical trials by Karelitz et al.<sup>1</sup> and by Weinstein.<sup>2</sup> The following investigations confirm their findings in a series of 97 additional penicillin-treated cases and present some clinical evidence bearing on the mode of action of this antibiotic.

#### MATERIAL

The material reported below consists of all patients admitted for diphtheria or the diphtheria carrier state to the 279th United States Army Station Hospital in Berlin, Germany, from July 1 to December 31, 1946. During the period of study diphtheria was constantly at epidemic levels, the troop rate being about 36/10,000 per annum, compared with the over-all rate for the city of 47/10,000 per annum. Cases in which the animal virulence test of the organism cast doubt on the original diagnosis have been eliminated from the study.

For comparison, an analysis was made of 50 consecutive cases of pharyngeal diphtheria admitted in the six months just prior to the study period and to the routine use of penicillin.

The average length of hospitalization of the non-penicillin-treated patients was fifty-seven days. Whereas all patients were hospitalized for a minimum of six weeks after onset, it is seen that 18 per cent of this series were held for a longer period because of minor cardioneurologic complications, and an additional 6 per cent were held for evacuation to the United States for more serious complications. There were 3 deaths in the series, giving a 6 per cent mortality. Omitting the above three categories, the average length of hospitalization of remaining patients rises to sixty-one days. The reason for this prolonged period of hospitalization becomes apparent when one notes that 57 per cent of the patients had to be held beyond the minimum six weeks merely because they continued to harbor virulent organisms in the nasopharynx. Such prolonged hospitalization of asymptomatic carriers represents a tremendous waste of hospital space and manpower.

#### PILOT STUDY

The routine use of penicillin in diphtheria treatment was based upon the results of a study of its effect upon 20 carriers selected on the following criteria: the patients were all asymptomatic convalescents so far as manifestations of acute diphtheria

\*Resident, Children's Medical Service, Massachusetts General Hospital.

were concerned, all had been hospitalized for six weeks or more since clinical onset, and from all, tri-weekly nasopharyngeal cultures were consistently positive for virulent diphtheria bacilli. During the study patients were isolated from new diphtheria contacts, usually 2 patients to a room, both receiving the same type of treatment.

Five cases were treated locally with sprays of a penicillin solution containing 500 units per cubic centimeter, applied to the nasopharynx every three hours day and night for ten days.

Seven cases were treated with 1,000,000 units of penicillin intramuscularly, the dosage schedule being 40,000 units every three hours for twenty-five doses.

Eight cases were treated parenterally with the same total amount of penicillin but given in doses of 20,000 units every three hours for fifty injections.

Cultures were taken three times a week during treatment. The carrier state was considered terminated if, at the completion of treatment, three consecutive

TABLE 1 *Results of Treatment in 20 Carriers Hospitalized for Six Weeks or More after Onset with Positive Cultures but No Symptoms*

TREATMENT	NO OF CASES	PATIENTS WITH NEGATIVE CULTURES %
Local nose and throat sprays of penicillin (500 units per cubic centimeter every 3 hours)	5	20
Parenteral administration of penicillin (40,000 units every 3 hours for 25 doses)	7	28
Parenteral administration of penicillin (20,000 units every 3 hours for 50 doses)	8	87

secutive cultures at forty-eight-hour intervals and a fourth culture one week later were negative.

Local treatment was followed by termination of the carrier state in only 1 patient. Although negative cultures were obtained during and for several days after the short course of parenteral therapy only 28 per cent of the series satisfied the criteria for termination of the carrier state. Excellent results, however, were obtained from the use of the same total dose given in smaller amounts over a longer period, only 1 patient failing to fulfill the criteria for permanent termination of the carrier state (Table 1). The necessity for the four-culture test for termination of the carrier state was demonstrated both in this pilot study and in the material to follow. In many cases the first culture or even the first three failed to show the organisms after penicillin treatment, though later cultures again revealed virulent diphtheria bacilli. On the other hand, no patient who had had the requisite four consecutive negative cultures showed virulent organisms when cultures were obtained on subsequent occasions.

## PROCEDURE BASED ON RESULTS OF PILOT STUDY

The results of the preliminary study were promising enough to warrant trial on a larger scale. In addition, it was presupposed that the value of penicillin was not limited to the treatment of carriers but that in acute cases its use might well be expected to reduce appreciably the number of patients continuing to carry virulent organisms for more than six weeks after clinical onset of the disease. Thus, penicillin was incorporated into the routine treatment of both carriers and acute cases.

Patients suspected of having acute pharyngeal diphtheria were immediately given a single average dose of 60,000 units of diphtheria antitoxin and in addition were started on three hourly doses of 20,000 units of penicillin (40,000 units in more severe cases). Penicillin was continued for seven days (fifty doses) or longer if the pharyngeal mucosa was not yet entirely healed.

Carriers were treated initially with the fifty-dose schedule. Only those who failed to respond to this routine were subjected to tonsillectomy. If cultures were still positive after penicillin and tonsillectomy a second identical course of penicillin was given.

## PENICILLIN TREATMENT IN ACUTE CASES

Forty-five cases of acute diphtheria were treated with penicillin during the six-month period of study. In comparison with the 50 previous cases, the average length of hospitalization was cut from fifty-seven to forty-five days. Two patients (4.4 per cent) developed serious cardioneurologic complications and were returned to hospitals in the United States. One patient (2.2 per cent) was held beyond the six weeks' minimum for minor cardioneurologic complications. There were no deaths. The average period of hospitalization, omitting the

TABLE 2 *Results of Treatment in 45 Cases\**

TREATMENT	NO OF CASES	NEGATIVE CULTURES AFTER TREATMENT NO PERCENTAGE
Penicillin alone (20,000 units every 3 hours)	45	40 80
Penicillin and tonsillectomy	5	4 80
Penicillin — tonsillectomy — penicillin	1	1 100

\*The average contagious period was 26.3 days from the time of admission in the fourth negative culture.

above three categories, dropped from sixty-one to forty-three and one-eighth days. Only three patients were held beyond the six weeks' minimum because of positive cultures, a reduction from 57 to approximately 9 per cent.

Table 2 shows a further analysis, including a summary of methods of treatment. The average "contagious" period — that is from admission to the time of receipt of the fourth negative culture after

treatment — was twenty-six and one-eighth days. All the 45 patients received an initial course of penicillin, usually consisting of fifty doses of 20,000 units each, however, a larger dose was sometimes given for the first three days. Forty patients, or 80 per cent, consistently showed negative cultures after treatment. Five patients regarded as penicillin failures, who still showed positive nasopharyngeal cultures at the end of six weeks, underwent tonsillectomy. Thereafter all but 1 showed negative cultures. This last patient was subjected to a second course of penicillin, 20,000 units every three hours for fifty doses, as a result of which there was a prompt termination of the carrier state.

#### PENICILLIN TREATMENT IN THE CARRIER STATE

During the period of study 52 chronic carriers of virulent *Corynebacterium diphtheriae* were treated. The average period of hospitalization following treatment was sixteen and a half days (Table 3).

TABLE 3 Results of Treatment in 52 Carriers \*

TREATMENT	NO OF CASES	NEGATIVE CULTURE AFTER TREATMENT	
		NO	PER CENTAGE
Penicillin alone (20 000 units every 3 hours for 50 doses)	44	37	87
Penicillin and tonsillectomy	13	12	92
Penicillin (2 courses)	1	1	100
Penicillin — tonsillectomy — penicillin	1	1	100

\*The average period of hospitalization after definitive treatment was 16.5 days.

Forty-four patients received an initial course of penicillin, consisting of 20,000 units every three hours for fifty doses. The carrier state was terminated in 37 cases, or 87 per cent. Six of these "penicillin failures" and 7 previously untreated cases were subjected to tonsillectomy, only 1 patient remaining a carrier after this procedure. One patient who failed to respond to the initial course of penicillin was desirous of undergoing a second treatment before submitting to tonsillectomy. This second course was given in the same manner as the first and resulted in cure. Finally, the patient who failed to respond to the initial tonsillectomy later underwent a course of penicillin. This resulted in clearing of a coexistent sinusitis and adenoid hypertrophy and was followed by four consecutive negative cultures at the prescribed intervals.

#### DISCUSSION

The results of the studies outlined above give further evidence of the value of penicillin as an adjunct in the treatment of diphtheria and the diphtheria carrier state. The present findings are in close agreement with those of Karelitz<sup>1</sup> and Weinstein.<sup>2</sup>

Tonsillectomy has long been recognized as the single most effective procedure in terminating the diphtheria carrier state. Adenoidectomy, the clearing of chronically infected accessory nasal sinuses, corrections of obstructive nasal septal deviation, dental surgery to eliminate foci of infection in the mouth and removal of foreign bodies occasionally found in the nasal passages of children are also well recognized surgical methods of importance in ridding the patient of organisms still obtainable on culture six weeks or more after the clinical onset of acute symptoms.

In general, modern antibiotics are obviating the necessity for much of the surgery of the presulfonamide days in diseases of bacteriologic etiology. This is true of diphtheria. The diphtheria bacillus is relatively resistant to penicillin<sup>3</sup> and quite resistant to sulfonamides.<sup>4</sup> Though it is sensitive to streptomycin,<sup>5</sup> there has been as yet no report of the clinical use of that drug. In the Schick-negative patient the bacillus is characteristically a surface-growing, noninvasive organism depending in large measure on devitalized organic detritus produced by the action of other bacteria to maintain its foothold in the human organism.<sup>6</sup> The surgical measures in common usage in diphtheria are effective because they mechanically eliminate such devitalized tissue. The rationale for the use of penicillin is based as much on its elimination of this detritus as on its specific effectiveness against the diphtheria organism. Here, in contrast to surgery, the site of action of penicillin is the varied organisms giving rise to hypertrophic and devitalized tissue. Three observations support the contention that this is an important factor in the effectiveness of penicillin. A certain class of carriers with necrotic, chronically infected tonsils that do not shrink in size with prolonged use of the antibiotic may confidently be expected to remain carriers until surgery is effected. Secondly, there is a class of patients with acute diphtheria in whom healing of the pharyngeal mucosa is still incomplete at the end of a week of treatment. If penicillin is discontinued according to rigid schedule after seven days (fifty doses), a high percentage of this group of patients will become chronic carriers. If, on the other hand, penicillin is continued a day or two longer until the pharyngeal tissues are re-epithelialized, almost none of the patients will subsequently show positive cultures. Thirdly, large doses of penicillin given over a short period are far less effective than small doses totaling the same amount but given over a longer period in shrinking and returning infected, hyperplastic pharyngeal lymphoid tissue to a healthy state. Corresponding with this is the superior effectiveness of small, longer continued penicillin doses in ending the diphtheria carrier state.

The present study does not suggest that penicillin supplant antitoxin in the treatment of acute diphtheria or replace surgery in the treatment of

he carrier. It indicates that penicillin is a valuable adjunct to antitoxin that should continue to be recognized as the specific form of treatment. Moreover, penicillin decreases the number of cases in which surgery is indicated, but does not lessen the necessity for operation in a selected group of patients.

### SUMMARY

An attempt to demonstrate the value of penicillin as an adjuvant to the treatment of diphtheria and the diphtheria carrier state is made through the presentation of the results of its use in 45 cases of acute diphtheria and 52 cases of carriers of virulent diphtheria organisms. For comparison these results are reported along with those obtained in treating 50 patients during the same epidemic but in the six previous months when penicillin was not used as part of the routine treatment.

The probable mode of action of penicillin is discussed.

It is concluded that penicillin is a valuable adjunct in the treatment of diphtheria and the diphtheria carrier state but that it does not supplant the use of antitoxin in the acute stage or obviate the necessity for surgery in a selected group of carriers.

## SURGERY OF ELEPHANTIASIS OF THE SCROTUM OF FILARIAL ORIGIN\*

CHARLES E. TOWNE, M.D.†

WATERVILLE, MAINE

A NEW interest in tropical diseases has been attained in American medicine because of the widespread contact with exotic diseases by troops in the worldwide conflict that terminated on V-J Day. Among these none is more bizarre than elephantiasis of *Filaria (Wuchereria) bancrofti* origin. This report deals with experience gained with this affliction among natives of Polynesian extraction in the Society Islands in French Oceania. I obtained the material for this paper in my capacity of chief of the Surgical Service of the 8th Station Hospital under the command of Lieutenant Colonel Julius Sobin, who performed the major part of the actual surgery and whose skill contributed in a large measure to the success of the enterprise.

The patients were studied for a period of twenty-six months on one of the Society Islands occupied by United States forces. Although inter-island traffic was limited to a degree by war conditions, blood tests were performed on hundreds of natives, revealing an incidence of microfilariae in some localities as high as 70 per cent. This incidence is about as high as that found anywhere in the world. De Rivas<sup>1</sup> states

In Polynesia, the micro-filariae show no periodicity and are present in the blood in about equal numbers both day and night. In other areas they show a nocturnal periodicity, it being definitely established that they are much more numerous in the peripheral blood at night than during the day.

### GENERAL DESCRIPTION

In filariasis associated with *W. bancrofti*, the adult parasites usually live in the lymph nodes and lymphatic vessels, and in connective tissues. After pairing, the females emit numbers of microfilariae, which reach the blood stream via the thoracic duct and by penetrating the thick walls of the lymphatic vessels into neighboring capillaries. The infection is transmitted from man to man by means of a mosquito, the species varying according to locality. In Polynesia two species, *Aedes variegatus* and *Culex fatigans*, are responsible. When the insect has sucked blood from a person harboring microfilariae, the parasites migrate to the insect's thorax and there undergo considerable development. In fifteen to twenty-one days the microfilariae become mature larvae and migrate to the head and then to the proboscis of the insect. If the mosquito sucks blood at this time, the parasites are able to find their way to the skin of the host and to penetrate it— independently of the wound made by the insect. The larvae, by an unknown process, reach sexual maturity when they find their permanent abode in the lymphatic vessels and lymph nodes within the host. They become adult worms and in a fresh state are

\*From the Thayer Hospital.

†Member surgical staff, Thayer Hospital.

yellowish white and transparent, resembling thin catgut. They frequently coil together, ten or a dozen being found in a single lymph node. The male is 4 to 4.5 cm long and 0.1 mm in diameter, whereas the female is twice as long and thick. The microfilariae are the product of conception of paired adult worms and are found in peripheral blood. Seen in a fresh smear, the microfilariae appear to be snake-like and exhibit twisting and lashing movements, but they do not progress, either laterally or longitudinally.

### PATHOLOGY

The disease evoked by infestation of lymphatic vessels by adult worms is at first a state of lymphangitis with all the signs of acute inflammatory reac-

FIGURE 1 Elephantiasis of the Scrotum in a Polynesian Native

tion. Very frequently secondary invaders, notably streptococci, cause abscess formation. After a few attacks there is a tendency to fibrosis and considerable hypertrophy of the lymphatic vessels. New and irregular formation of lymphoid tissue surrounded by fat succeeds each attack. An elephantoid process forms by repeated attacks, with predilection for the breast in the female and the scrotum in the male. A typical case of scrotal elephantiasis is illustrated in Figure 1. It is my opinion that these organs favor elephantoid development because of their more dependent lymphatic circulation, which in turn encourages the mechanical obstruction that is always the cause of elephantiasis.

### CLINICAL MANIFESTATIONS

Many people infected with filariasis suffer no inconvenience whatever. Thousands of troops stationed in the Pacific became infested with *W. bancrofti*. Between 1942 and 1945 in all theaters of war Saper<sup>2</sup> estimated that 14,000 members of the armed forces contracted filariasis. Predominantly, the infestation was acquired in the Pacific Theater. Had it not been for the marvelous efficiency of service troops in mosquito-control units, there would undeniably have been a much higher incidence of occurrence than that reported. These units operated in areas of malaria, filariasis and other tropical diseases with great efficiency, mainly by ditching, draining, spraying with DDT and other insecticides, screening and by education of both troops and natives in methods of mosquito control. The troops that became afflicted by repeated bites from infected mosquitoes exhibited early signs of the disease, usually either an acute funiculitis or epididymitis or a superficial lymphadenitis.

When the patient was transferred to a nonfilarial area, the entire symptomatology faded away, and follow-up study in all these cases has shown an almost universal recovery, with practically no recurrence.

On the other hand by repeated attacks about 50 per cent of the natives had a large variety of symptoms, and 5 per cent had elephantiasis. The more usual conditions were lymphangitis and adenitis, elephantoid fever and elephantiasis, abscess, inflammation of the spermatic cord and epididymis, hydrocele, cystic enlargements of the skin, lymph nodes and breasts, fistula, chyluria and chylous conditions of the peritoneum and intestine, and chylocele synovitis.

### DIAGNOSIS

The recovery of living or dead calcified parasites in a lymph node or abscess and the occurrence of microfilariae in the blood constitute positive diagnostic data. However, the microfilariae frequently disappear from the blood after elephantiasis has occurred, owing to death of the parent parasites within the body of the host. Matas<sup>3</sup> states that recurrent erysipelatous inflammation with progressive hypertrophy is diagnostic.

Blood studies may be of value. The presence of eosinophilia in the absence of intestinal helminthiasis is suggestive. At the height of the attack the eosinophil count may rise to 25 or 30 per cent. Recently, O'Connor<sup>4</sup> has used x-ray examination to demonstrate the presence of calcified worms, a new aid in diagnosis.

### SURGERY OF SCROTAL ELEPHANTIASIS

There is little in the American medical literature denoting the technic of surgery on the patient with scrotal elephantiasis, because of an almost total lack

of patients with this affliction within the continental limits of the United States. French and South American surgeons have had great opportunity to pioneer in this field and have published reports of successful surgery performed in scattered areas of the globe. Since the pathologic findings vary materially in different locations, the surgeon, perforce, must adapt his technic to suit the conditions. There is no one type of operative procedure that will answer all the needs as found in various locations. A search of the literature discloses exactly the same number of technical approaches as the number of writers. Certain basic features however are constant findings in these reports:

Infection is always present, and precautionary measures must be adopted. Bankoff<sup>5</sup> states that 95 per cent of the cases will suppurate, adding "The complication can be eliminated today by packing sulfonamide powder directly into the wound."

Preservation of the penis and testes is vital. In some locations scrotal elephantiasis is always accompanied by hydrocele, which must be handled with the established surgical procedure of excision.

Hemostasis and control of bleeding are axiomatic. de Savitsch<sup>6</sup> points out the universal need of applying a tourniquet at the base of the scrotum and doubly ligating the large blood vessels found medial to the cord to avoid the serious consequence of hemorrhage.

In this series of 24 cases the scrotum was universally affected on both sides, with concomitant bilateral hydrocele. The hydroceles were usually disproportionate in size, giving the appearance of more scrotal involvement on the side of the larger hydrocele. Since many patients had skin manifestations of yaws as well as filariasis, they were given three intravenous treatments of arsphenamine before hospitalization. This always sufficed to eradicate yaws as a possible contaminating agent.

The average age was thirty-eight years. The scrotal elephantiasis had been present for an average of eight years, and the scrotal redundancy averaged 15 pounds, which does not include the fluid contained within the hydroceles.

Sexual intercourse was impossible for the patients prior to operation because the penis was deeply imbedded within the tumor mass. These people were Polynesians, and whereas this paper is not intended to deal with ethnology, it should be remarked that the male Tahitian is brown-skinned, extremely muscular and well nourished and, despite his filarial infestation, a very healthy being. Under these conditions it was not necessary to build up the patient prior to surgery by the use of hematinics, vitamins, amino acids or chemotherapy. It was enough to rid him of yaws and to sterilize the skin locally.

Under ether anesthesia the patient received his final skin preparation, and an elastic tourniquet was placed tightly around the scrotum and as near the perineum as possible. The penis was located by palpation and held away by the assistant's right hand. The surgeon then located the testicle on one side and exposed it by a lateral incision. The hydrocele, which was always present, was corrected by an inversion procedure. The same surgery was repeated on the other side. It was not necessary to provide a pulley attached to the ceiling to elevate the tumor mass, as reported by de Savitsch.<sup>6</sup> The large blood vessels were isolated, doubly ligated and divided as high as possible.

In the next step the two lateral incisions were extended on each side of the mass in a curvilinear direction, meeting in the midline posteriorly. Anteriorly, the lateral incisions were joined by a long straight flap, which provided skin for a new sheath for the penis in the event that it was found necessary to sacrifice the integument of the old sheath. However, the sheath in each case was found to be resilient — in fact, quite normal — and to have no relation to the extremely fibrotic and thickened skin of the scrotum. The main tumor mass was then amputated distal to the lines of the incisions, and all bleeding vessels were carefully ligated after removal of the elastic tourniquet.

In reports from other localities — notably, the French Congo — the surgeons had to borrow skin from normal sites to provide new sheath and the new scrotum, but in the present report this was not necessary owing to the integrity of the old sheath and to undermining of the skin of the remaining scrotal flaps. The wound was dusted with sulfonamide powder and closed lightly with nonabsorbable suture material. A rubber dam was inserted in the most dependent part of the wound, and a thick gauze was secured by a T binder. Postoperatively the wounds healed rapidly and with only moderate infection. Usually in ten days the patient was discharged from the hospital to resume his usual haunts, unencumbered by his previous disability and once again able to cope with economic and social obligations.

Military horizons were extended. The Army moved on to new shores, and the results could not be observed over a sufficient period for a report on long-term postoperative findings. It was obvious, however, that psychologically the patients were extremely benefited. There were no indications of impending recurrence of elephantiasis in any case.

#### SUMMARY

A description of elephantiasis of the scrotum of filarial origin among natives in Polynesia is presented. The mosquito vectors are named, and a general picture of the resulting pathology is described.

yellowish white and transparent, resembling thin catgut. They frequently coil together, ten or a dozen being found in a single lymph node. The male is 4 to 4.5 cm long and 0.1 mm in diameter, whereas the female is twice as long and thick. The microfilariae are the product of conception of paired adult worms and are found in peripheral blood. Seen in a fresh smear, the microfilariae appear to be snake-like and exhibit twisting and lashing movements, but they do not progress, either laterally or longitudinally.

### PATHOLOGY

The disease evoked by infestation of lymphatic vessels by adult worms is at first a state of lymphangitis with all the signs of acute inflammatory reac-

FIGURE 1 Elephantiasis of the Scrotum in a Polynesian Native

tion. Very frequently secondary invaders, notably streptococci, cause abscess formation. After a few attacks there is a tendency to fibrosis and considerable hypertrophy of the lymphatic vessels. New and irregular formation of lymphoid tissue surrounded by fat succeeds each attack. An elephantoid process forms by repeated attacks, with predilection for the breast in the female and the scrotum in the male. A typical case of scrotal elephantiasis is illustrated in Figure 1. It is my opinion that these organs favor elephantoid development because of their more dependent lymphatic circulation, which in turn encourages the mechanical obstruction that is always the cause of elephantiasis.

### CLINICAL MANIFESTATIONS

Many people infected with filariasis suffer no inconvenience whatever. Thousands of troops stationed in the Pacific became infested with *W. bancrofti*. Between 1942 and 1945 in all theaters of war Saper<sup>2</sup> estimated that 14,000 members of the armed forces contracted filariasis. Predominantly, the infestation was acquired in the Pacific Theater. Had it not been for the marvelous efficiency of service troops in mosquito-control units, there would undeniably have been a much higher incidence of occurrence than that reported. These units operated in areas of malaria, filariasis and other tropical diseases with great efficiency, mainly by ditching, draining, spraying with DDT and other insecticides, screening and by education of both troops and natives in methods of mosquito control. The troops that became afflicted by repeated bites from infected mosquitoes exhibited early signs of the disease, usually either an acute funiculitis or epididymitis or a superficial lymphadenitis.

When the patient was transferred to a nonfilarial area, the entire symptomatology faded away, and follow-up study in all these cases has shown an almost universal recovery, with practically no recurrence.

On the other hand by repeated attacks about 50 per cent of the natives had a large variety of symptoms, and 5 per cent had elephantiasis. The more usual conditions were lymphangitis and adenitis, elephantoid fever and elephantiasis, abscess, inflammation of the spermatic cord and epididymis, hydrocele, cystic enlargements of the skin, lymph nodes and breasts, fistula, chyluria and chylous conditions of the peritoneum and intestine, and chylocele synovitis.

### DIAGNOSIS

The recovery of living or dead calcified parasites in a lymph node or abscess and the occurrence of microfilariae in the blood constitute positive diagnostic data. However, the microfilariae frequently disappear from the blood after elephantiasis has occurred, owing to death of the parent parasites within the body of the host. Matas<sup>3</sup> states that recurrent erysipelatous inflammation with progressive hypertrophy is diagnostic.

Blood studies may be of value. The presence of eosinophilia in the absence of intestinal helminthiasis is suggestive. At the height of the attack the eosinophil count may rise to 25 or 30 per cent. Recently, O'Connor<sup>4</sup> has used x-ray examination to demonstrate the presence of calcified worms, a new aid in diagnosis.

### SURGERY OF SCROTAL ELEPHANTIASIS

There is little in the American medical literature denoting the technic of surgery on the patient with scrotal elephantiasis, because of an almost total lack

direction of research must be based on theory rather than fact. As an example of this, some representative attitudes on cancer chemotherapy have been culled from the recent literature

Woglom<sup>1</sup> has summarized, in a rather caustic fashion, the efforts to treat cancer by means of tumor extracts or autolysates, organ extracts, enzymes, metals, agents interfering with aerobic glycolysis, fever, cold, dyes, snake venoms, vitamins, various chemicals and a number of miscellaneous substances. His review indicates that many thousands of remedies have been tried in the treatment of cancer, that reports of favorable results usually originate from quacks or deluded or ignorant men and that the possibility of finding a cure for cancer is next to impossible.

Haddow<sup>2</sup> has set down more explicitly the difficulties of discovering a specific therapeutic agent against cancer.

It has always been a matter for legitimate doubt whether a therapeutic agent could impair the growth of malignant cells, without equally damaging the normal cells and especially those which are engaged in active division, for example, in the intestinal mucosa, the bone marrow, and the generative organs. An even more serious obstacle is the fact that the malignant variant is to all intents and purposes quite permanent and irreversible. Hence, even if its growth is impeded by any agent save the most specific (so far unknown), it is likely after a longer or shorter interval, to recover and recur. There can be no misunderstanding as to the almost insuperable problem which the chemotherapy of cancer presents, and which, in search of a comparison, we can almost liken to a biological counterpart of the squaring of the circle. It is indeed true that those who have considered the matter most thoroughly are under the least illusion as to its practicability.

In spite of these real impediments, Haddow has formulated his attack on the problem as follows: "the best prospects of success should come from persistent investigation of the mode of action of carcinogens, so that by increasingly exact and quantitative knowledge of the process as it occurs in one direction, we may estimate at any rate the feasibility of its deliberate reversal."

Burk,<sup>13</sup> on a premise elaborated in a recent book by Greenstein,<sup>14</sup> writes more optimistically:

The hope for the (chemical) approach lies mainly in the finding of modern biochemistry that whereas etiologically and morphologically cancer represents a great group of diseases, biochemically it presents a surprisingly uniform metabolic, chemical pattern that is characteristic, and therefore potentially subject to a unique or reasonably small number of chemotherapeutic agents, just as large classes of pathogenic microorganisms now are. The established biochemical "much of a muchness" of cancers may be regarded as a by-pass to an otherwise seemingly endless complexity of the problem.

Algire<sup>15</sup> has stated the belief that a common factor in the neoplastic process is the stimulation to the formation of new capillaries.

It should be emphasized that an outstanding characteristic of the rapidly growing tumor is its capacity continuously to elicit the production of new capillary endothelium from the host. This characteristic of the tumor cell might possibly be the real underlying factor respon-

sible for the autonomous growth inherent within the tumor cell, and from the standpoint of the host this capacity would seem to be a critical if not the critical expression of the neoplastic change. Since in tumor regression this ability to elicit a continuing vascular proliferation is lost, from the broad viewpoint of tumor therapy the study of the mechanism of this continuous vascular proliferation presents a major problem in cancer research.

On this basis, it appears that a study of agents interfering with capillary proliferation might furnish a generally useful chemotherapeutic agent against cancer.

The virus theory of cancer has been most persuasively presented by Oberling.<sup>16</sup> In this theory, however, the ubiquitous, tissue-specific viruses are presumably numerous and different so that it is difficult to imagine a common chemotherapeutic agent acting on all of them. If one can accept the virus hypothesis it does not seem much more

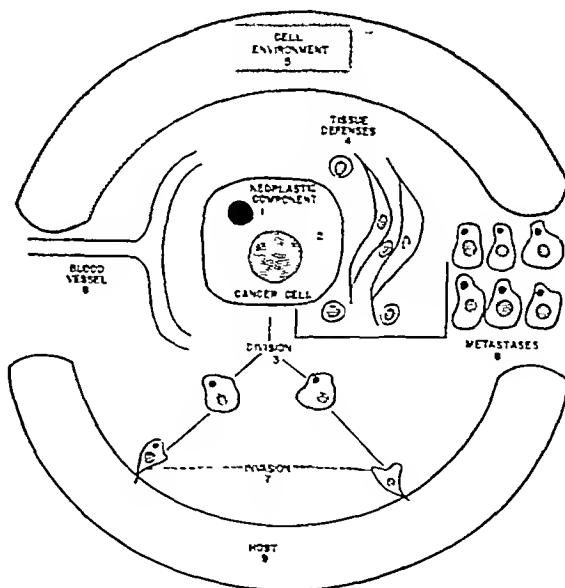

FIGURE 1 Diagram of the Possible Points of Attack by Chemotherapeutic Agents on Cancer and Its Manifestations (Reproduced from Karnofsky<sup>12</sup> by Permission of the Publishers)

difficult to conceive of a single agent or series of agents interfering with the proliferation or activity of these viruses.

Using the broad definition that "cancer chemotherapy is the use of any chemical substance administered systemically which, while relatively nontoxic to the host, will interfere with favorably modify, or destroy a neoplastic growth or alleviate its deleterious effects on the host," Karnofsky<sup>12</sup> has discussed the various possible avenues of chemotherapeutic attack on cancer, these are shown in Figure 1, with examples from agents under current study. The possible effects are as follows.

It is pointed out that veterans who had contracted the infestation during wartime have made virtually 100 per cent recoveries after their return to nonfilarial areas

Drug treatment of filariasis has been attempted with no great success throughout the regions where it occurs. Surgery offers the only benefit to those who have acquired elephantiasis as a result of many repeated bites of infected mosquitoes.

The technic of a surgical approach to the problem of elephantiasis of the scrotum is presented

50 Main Street

## MEDICAL PROGRESS

### CHEMOTHERAPY OF NEOPLASTIC DISEASE

#### I. Methods of Approach

DAVID A. KARNOFSKY, M.D.\*

NEW YORK CITY

**I**N RECENT years there has been a remarkable increase in research directed toward the discovery of chemical substances of therapeutic value in neoplastic disease. This endeavor has been stimulated by many factors: the intensification of medical research in general and cancer research in particular, the notable examples set by the development of antibiotics for bacterial infections, public demand for effective methods of controlling the disease, and the ever-present, suffering, doomed, but often lingering, patient with cancer. Recent chemotherapeutic advances — estrogens in prostatic carcinoma, nitrogen mustards in the lymphomas and urethane in the leukemias — have provided some encouragement toward the solution of a problem that has been viewed with unrelieved pessimism by many experienced investigators.<sup>1</sup>

One of the chief objectives of cancer research is the development of effective therapy. With the belief that methods of treatment will follow from an understanding of the disease itself, many investigators concentrate their efforts on the biologic and chemical aspects of cancer. Others, with more faith and often less method, are directly concerned with the therapeutic problem. Investigations in cancer chemotherapy are in progress at the National Cancer Institute<sup>2</sup> and at a number of universities and hospitals. Many projects of this type are sponsored by the American Cancer Society on recommendation of the Chemotherapy Section of the Committee on Growth of

the National Research Council.<sup>3</sup> Some pharmaceutical companies, which routinely test new chemicals against a variety of infectious organisms and in various biochemical systems, now include in these tests the neoplastic cell. In short, a great and direct effort on the problem of cancer chemotherapy is underway. This is evidenced by the numerous reviews that have appeared on the subject since 1945.<sup>4-12</sup>

It seems appropriate to review the basic ideas, the laboratory technics and the methods of clinical evaluation established in the cancer-chemotherapy program, and to discuss the status of the agents that have been proposed, utilized or publicized as having a role in the treatment or management of cancer in man. At present the problem has attracted the attention of most of the scientific disciplines and of many clinical investigators. The modern approach is still in its formative phase, and there is a great deal of room for controversy and differing opinions.

It is hoped that this brief review will help to clarify the several aspects of the complex field of cancer chemotherapy, and substitute concrete expression for what often seems to be wishful thinking.

#### APPROACHES TO THE PROBLEM

It may be assumed that, if the proper approach were known, the attempt to discover curative drugs for cancer would be immensely simplified. Since, unfortunately, there are many conceptions of the chemotherapy problem, none of which is generally acceptable and all of which may be untrue, the

\*Associate Sloan-Kettering Institute for Cancer Research, fellow in medicine, Memorial Hospital Center for Cancer and Allied Diseases, fellow, Jane Coffin Childs Memorial Fund for Medical Research.

are being used, and some of these are briefly described below

The most common methods involve the use of *transplantable solid tumors* in mice or rats

The National Cancer Institute uses the Sarcoma 37, inoculated intramuscularly into the flank of the mouse. The chemotherapy screening technic is described as follows<sup>18</sup>

Injection into mice, bearing a 1-week-old implantation of Sarcoma 37, of a single, maximum tolerated dose. The injection is made into the flank opposite the side bearing the tumor. Sacrifice of the mice at 8, 20, and 48 hours after the injection. Recording of the gross autopsy findings. Fixing of tumor tissue in Zenker-acetic and in acetic-orcein. The wall of the small intestine is taken as control tissue. Evaluation of the cellular changes produced by the treatment.

This test may disclose substances injurious to rapidly dividing cells or to newly formed capillaries, and it may possibly disclose an agent selectively injurious to tumor cells

A somewhat similar method is described by Laszlo and Leuchtenberger<sup>19</sup>. A transplantable tumor, the Sarcoma 180, is inoculated subcutaneously in mice. One week later, when the tumor is definitely palpable, the test material is injected twice daily for two days, and then the tumors are removed and weighed, and the weights compared with appropriate controls

In another type of experiment, a tumor is transplanted subcutaneously and observed for an arbitrary period, or until growth is well established. Treatment may then be instituted in several ways: the agent may be given by mouth<sup>20</sup> or by parenteral injections<sup>21</sup>. The mice may be observed for a standard period, and the size of the treated tumors compared with the controls, or observed indefinitely until the tumor kills the animal or until complete tumor regression occurs. The size of the tumor at death, the incidence of tumor regression or the survival time of the tumor-bearing mice may be used as criteria of effect. The weights of the mice must be observed during therapy, since starvation<sup>22</sup> or nonspecific intoxication may influence tumor growth<sup>23</sup>.

Recently, *transmitted leukemia* has come into more prominent experimental use<sup>24-26</sup>. Susceptible mice are inoculated intraperitoneally or intravenously with a suspension of leukemic cells. Therapy is begun shortly afterward, and is usually continued at the maximum tolerated dose for several weeks. The survival time of the treated as compared with the untreated mice is used as an index of the therapeutic efficacy of the test agent. This procedure will disclose drugs that inhibit rapidly growing cells or selectively inhibit neoplastic cells. It is possible, however, that some drugs increase survival time indirectly by supporting the mice against the systemic consequences of leukemia without acting directly on the neoplastic cells.

Transplanted tumors or leukemia are most practical for the screening of chemotherapeutic agents. In animals bearing transplanted tumors, however, the host-tumor relation usually must be considered abnormal, and a more critical evaluation of chemotherapeutic activity may be conducted in mice with *spontaneous* or *carcinogen-induced* tumors. Suitable groups of these mice are often difficult to obtain. It must also be realized that each spontaneous tumor has its own characteristic properties and rate of growth, survival time and tumor regression studies must therefore be carried out on larger numbers of mice than are necessary with the standardized method in which the disease is transmitted. Usually, if an agent is effective against transplanted tumors, confirmatory tests are run on spontaneous or carcinogen-induced tumors.

A *cytotoxic technic* for determining the dosage of a chemical necessary to inactivate tumor cells *in vivo* has been described by Burchenal<sup>27</sup>. This method is applicable to drugs that do not kill the test animal immediately, even when given at several multiples of the LD<sub>50</sub>\*. Mice with established transmitted leukemia are injected with various multiples of the LD<sub>50</sub> of the test substance. At an arbitrary period after injection, or just before death, the animal is sacrificed and a suspension of its leukemic cells (usually a splenic suspension) is injected into susceptible mice to determine their viability. This method is also applicable to solid tumors<sup>28</sup>. A drug that causes no obvious cytologic effects in a tumor at sublethal doses may produce significant effects when given at supralethal doses.

An *egg-culture method* has been described in which the test object is the Sarcoma 180 (a mouse tumor) growing on the chorioallantoic membrane of the chick embryo<sup>28</sup>. The tumor fragment is implanted on the eight-day embryo, when the presence of an active growth is demonstrated four days later, the maximal dose of the test chemical tolerated by the egg is injected into the yolk sac. Five days after injection the Sarcoma 180 is removed and examined for size, histologic appearance and viability, by transplantation into mice. The method, although limited in application, permits a comparison of the effects of chemicals on a variety of actively growing embryonic and tumor tissue, it may also reveal differences in the inherent susceptibilities of mouse and chick tissues.

Tumors in fowls are usually associated with a filtrable agent. The Rous sarcoma virus has most frequently been used in chemotherapeutic studies. It may be implanted in young chicks<sup>29</sup> or on the chorioallantoic membrane of the chick embryo<sup>30</sup> and the number of "takes" and rate of tumor growth measured. Another technic is the determination of the concentration of the test substance *in vitro* that is necessary to inactivate the infectivity

\*The smallest amount of the drug necessary to kill 50 per cent of the animals within the test period.

1 On the neoplastic component of the cell, which may be a single substance or a physiologic process occurring primarily anywhere in the cell

2 On the normal cell, which is the portion of the neoplastic cell that retains the functional and chemical characteristics of normal tissues and the tissue of origin — for example, nitrogen mustards, urethane and radioactive iodine

3 On the dividing cell, mitosis being essential for the manifestations of the neoplastic process — for example, colchicine

4 On the tissue defenses, suggesting that in some cases the tissues develop a defensive reaction against cancer

5 On the cell environment, on the basis that the growth of certain normal tissues depends on the presence of specific substances in their environment — for example, estrogens

6 On damage to the blood supply, on the basis that cancer tissue requires a good blood supply for growth — for example, Shear's polysaccharide

7 Stopping the invasiveness of cancer

8 Preventing the development of cancer metastases

9 Protecting or strengthening the host against the systemic derangements produced by certain types of tumors

In the absence of any known method of attacking the neoplastic process directly, any substance that may indirectly injure or influence the cancer cell should be considered suitable for clinical trial. Since the possibility of achieving a universal cancer cure seems to lie in the far distant future, "the cancer chemotherapist has progressively lowered his objectives from finding substances which will cure only certain types of cancer, to substances which will control cancer or certain types of cancer or certain manifestations of cancer, and, finally, to substances that have only a temporary palliative effect on the disease"<sup>12</sup> Most of the agents that have been considered suitable for inclusion in this review belong to the last group

#### LABORATORY TECHNICS

Special laboratory technics, involving the use of neoplastic cells and tissues, have been developed to test substances in a preliminary and general fashion for any selective activity against cancer (screening methods), to examine the mechanisms whereby certain substances affect the growth of tumors and to compare quantitatively the chemotherapeutic activity of different members of a given group of substances. In principle, these methods have much in common with those used in bacterial chemotherapy. However, they are more complicated and require more time than antibacterial methods, the results are less reproducible, and the data obtained are, consequently, more difficult to analyze. Further-

more, the validity of conclusions drawn from these data, in terms of the efficiency of an agent in affecting neoplastic as compared with normal cells, is often open to question. Because these methods are in current use<sup>17</sup> and represent an important part of any chemotherapeutic program, it is necessary to review them briefly.

The tumor-bearing mouse is the most commonly used tool in cancer chemotherapeutics, the rat, rabbit and chicken are employed to a lesser extent. Mice can be inbred with relative ease to the point of being homozygous, and strains of mice have been inbred for selected characteristics such as a high incidence of spontaneous leukemia and mammary carcinoma. Tumors of certain types may also be regularly induced by carcinogenic compounds. Within appropriate strains of mice, tumors may be easily and consistently transplanted, and a host of different transplantable tumors are available.

This variability of material and also of testing procedure must be carefully considered in any chemotherapeutic screening program. For example, the sex, strain, degree of inbreeding or homogeneity, age and nutritional and reproductive status of mice may vary. Tumors may be spontaneous, carcinogen induced or transplanted, and they may differ in their site of origin, histologic structure, rate of growth, ability to metastasize, sensitivity to various procedures and ability to grow in heterozygous mice. In the performance of a chemotherapeutic experiment on tumor-bearing mice, the test substance may be given orally, subcutaneously, intraperitoneally or intravenously, it may be given in the maximum tolerated dose, or at a fraction of this dose, or administered as a single dose, or given repeatedly over a period, and it may be administered in combination with other agents. Therapy may be started when the tumor is transplanted or when it is first palpable, or when it reaches a certain size, or a certain number of days after transplantation. In examination of the mouse for evidence of chemotherapeutic effect, tumor injury may be measured by evidence of histologic damage, by change in the size of the tumor or by the survival time of the tumor-bearing mouse.

In vitro tests, egg culture and tissue culture are additional methods currently in use. Thus, an almost infinite variety of chemotherapeutic experiments is possible. Since it is not "logistically" feasible to run all possible variations of these methods for each compound, it is conceivable that the activity of a highly specific drug, effective against a certain tumor in a certain strain of mouse under certain conditions of administration, would be missed in arbitrarily selected procedures. It is more reasonable to assume, however, that a therapeutically active substance will have a broad range of activity, even though its effectiveness within this range may vary considerably. On the latter basis a number of arbitrarily designed testing technics

### CASE 34321

#### PRESENTATION OF CASE

A fifty-five-year-old businessman entered the hospital because of abdominal pain and vomiting. One night six weeks before admission the patient awoke feeling nauseated and subsequently vomited several times. There was no pain. Business and family worries had been plaguing him and for several months he had felt tense and nervous. After this episode he remained in bed four days and then returned to work. Late at night, following days on which financial problems had been particularly trying, spells of painless vomiting would recur. Two weeks before admission he left work. The nocturnal

vomiting became more frequent and began to be accompanied by severe cramps, starting in the back and radiating around to the midline in a vise-like manner. He was given pills and put on a bland diet without relief. Two days before admission the frequency of vomiting increased to every two or three hours, no food or fluid was retained. The vomitus consisted of food, fluid and mucus without blood. The bowels had been moving only with laxatives or with enemas. The stools were of normal color. During this illness there was a 25-pound weight loss.

During examination the patient was tense and uncomfortable, constantly shifting position in an effort to relax. When activity reached a peak, he vomited. The speech was rambling, and he had difficulty recalling dates and time. The heart was normal. There was dullness over the left lower lobe posteriorly and in the left axilla, breath sounds and tactile fremitus being reduced in the same areas. The abdomen showed tenderness and spasm throughout the epigastrium. Peristalsis was active. There were no masses.

The temperature was 98.6°F, the pulse 88 and the respirations 20. The blood pressure was 135 systolic, 90 diastolic.

Examination of the blood revealed a white-cell count of 9600. The hemoglobin was 14.6 gm. There was a + test for albumin in the urine, and rare casts were found. The icteric index was 13.

of the virus. Similar studies have been conducted with fowl leukosis in chicks.<sup>31</sup>

Several types of technics have been used *in vitro* to measure the toxicity of certain agents to neoplastic cells, or to detect a selective toxicity to neoplastic tissue by comparison with normal tissue of similar origin. These procedures are particularly useful when only small amounts of the test substance are available.

**Tissue culture.** Normal and neoplastic cells are explanted under similar conditions, and the effects of the test substances, as measured by their lethal effect or a specific type of cellular injury to the explant, are determined. The susceptibility of normal and neoplastic cells to the test substance is compared, and the procedure may reveal an agent selectively injurious to neoplastic cells. Ormsbee, Cornman and Berger<sup>32</sup> have described a method of grading the condition of explanted tissues, so that a numerical index of injury can be obtained. The ratio between the injury produced by a given agent in the neoplastic and in the normal tissue is known as the "selective index."

**Chemical toxicity.** Sugiura<sup>33</sup> and others have placed small pieces of mouse tumor in a solution of the test agent for a prescribed period at certain temperatures (one test is run at 2 to 4°C for twenty-four hours), after which the fragments are assayed for viability in susceptible mice. The index of effect is the percentage of "takes" and their rate of growth. This method measures the toxicity of chemicals to cells, but it provides no evidence for a selective effect on tumor cells. Another variation in this method is to place slices of tumor tissue and of normal liver tissue in serum containing the test substance at 37°C for twenty-four hours and then to examine the tissues histologically.<sup>34</sup> A selective effect is shown if the normal tissue appears unaltered in the presence of damaged neoplastic tissue.

**Metabolic studies *in vitro*.** Suspensions or slices of normal and neoplastic tissue are placed in the Warburg apparatus, and the test substances are added. Selective inhibition of the tissue respiration of the neoplastic compared with the normal tissue is the measure of effect.<sup>35</sup>

None of the methods in use appear to be entirely satisfactory in disclosing agents that have a selective action on tumor cells. One of the important fields in cancer research is the development of more precise methods for testing substances in the laboratory for chemotherapeutic activity.

#### CLINICAL TESTING OF CHEMOTHERAPEUTIC AGENTS

The clinical investigation of various substances for therapeutic activity in cancer still remains, in large part, a program distinctly separate from the laboratory "screening procedures." Most of the laboratory procedures are designed to disclose substances that are selectively injurious to tumor cells,

either temporarily damaging, or inhibiting, or destroying neoplastic cells in the presence of normal cells. The discovery of such substances in the laboratory and subsequent proof of their effectiveness in patients with cancer would be of extreme importance to the clinician. In the meantime, the clinician is faced with the problem of palliating or attempting to control definite clinical entities that fall in the category of neoplastic diseases. He cannot depend entirely on the laboratory "screening" results to give him substances for therapeutic trials; he must be able to borrow from the fields of biochemistry, pathology, physiology, pharmacology, endocrinology and toxicology. For example, certain cancers may be controlled by influencing the non-neoplastic properties of cells persisting from their tissue of origin; this technic is particularly effective if the tissue from which the cancer arises is not essential to life. Without undue injury to the organism, the prostate may involute almost completely, in some cases, with stilbestrol therapy, or the thyroid gland may be severely damaged by radioactive iodine through its ability to concentrate iodine selectively, if cancers, arising from these tissues, retain their characteristic physiologic properties; they will also be adversely affected by these agents. General cell poisons may depress certain neoplastic cells to a greater degree and for a longer period than they depress the normal tissue of their origin and, thereby, produce some clinical benefit. Secondary manifestations of tumor growth may be combated by general therapeutic measures appropriate for the organ or system involved or for the physiologic derangement present. The clinician will therefore obtain suggestions for clinical trials from many sources, of which a relatively limited one, at present, is the laboratory screening program.

If a compound is to be studied clinically, pharmacologic data and, if obtainable, the mechanism of action *in vivo* should be available before the treatment of patients is begun. It is apparent that a more complete, coherent and critical clinical study can be carried out if there is some indication of how the patient and disease will be affected by the agent. Experience has shown that the clinical evaluation of an agent producing only palliative effects may be an extremely difficult project, an effective form of therapy may be overlooked owing to an inadequate clinical trial, and ineffective treatments have been used for many years because of the lack of a convincing body of negative data. These problems are well known to clinicians familiar with cancer, and they have recently been discussed in detail.<sup>36</sup>

rampy' pains in the back suggest penetration of an ulcer in the pancreas. The tenderness in the epigastrium can again be caused by a penetrating ulcer. Many hold an opinion that tenderness does not occur with a duodenal ulcer until there is penetrating involvement of either the pancreas or peritoneal surface of the duodenum. So much for the ulcer. It will not explain such things as the fluid in the chest, the mass in the midepigastrium, and probably the jaundice.

What next? Gallstones should be considered. The patient had recurrent pains in the back and whenever one elicits this fact one must think of gallstones as well as peptic ulcer. Moreover, with this recurrent periodic pain there was associated nausea and vomiting. If jaundice appears, it is even more suggestive of gallstones obstructing the common duct. Unfortunately, there should have been fever and leukocytosis for the diagnosis of gallstones. Unless there were complications from the gallstones, he should not have had this mass in the midepigastrium and the fluid. One could suggest that the gallstone had perforated into the lesser omental cavity, and that the patient then developed an abscess of the lesser omental cavity. It could then cause inflammatory obstruction of the common duct and perhaps extension of fluid through the left leaf of the diaphragm. We might even consider that because of this mass the splenic vein had been involved with thrombosis and, ergo, a large spleen. It is a good story but we have no elevation of the white-cell count and no fever to go with it.

Another possibility is that a person with severe pain in this region and a mass, which might be a pancreatic cyst, could have chronic recurrent pancreatitis or acute pancreatitis. So far as acute pancreatitis is concerned, this man was sick enough but he did not have a high white-cell count, he did not have a high temperature, he had no board-like abdomen—in fact, nothing to go with acute pancreatitis except for the serum amylase of 78 units. In this hospital the serum amylase is so variable that we cannot put much emphasis on a single determination. If we had had another determination, either twelve or twenty-four hours before that, and if it had been approximately 30 units, or another twenty-four hours later and had it been around 125 to 150 units, we could say that the serum amylase was significant. This 78 units was an isolated reading. A determination of 50 or 55 units is considered the upper limit of normal. With an amylase of 78 units if we wanted to "go out on a limb," we could say that this man had pancreatitis. So we are left somewhat in a quandary.

I have covered the essentials of my differential diagnosis and I still have not considered one point, that is, the rambling speech and difficulty in recalling dates and time. I am frankly stumped as to how to explain these neurologic changes. It is possible that excessive electrolyte depletion due to the

vomiting was the basis for this neurologic manifestation. We know that some decompensated cardiac patients, who are treated intensively with salt restriction and dehydration, are "out in left field" because of hyponatremia.

I am sure I shall be wrong but I am going to say that he had carcinoma of the pancreas, with possible involvement of the splenic vein and thrombosis to explain the enlarged spleen, metastases to the left pleura to explain the fluid in the left chest and that he developed a cyst of the pancreas, secondary to the cancer.

#### CLINICAL DIAGNOSIS

Acute pancreatitis?

#### DR CULVER'S DIAGNOSES

Carcinoma of pancreas

Pancreatic cyst.

Metastatic cancer of left pleura

Splenomegaly due to thrombosis of splenic vein

#### ANATOMICAL DIAGNOSES

*Carcinoma of pancreas, with extension to stomach, transverse colon, and spleen, with metastases to retroperitoneal lymph nodes, lungs and kidney*

Hydrothorax, bilateral

Pulmonary atelectasis, left lower

Operations cholecystostomy and jejunostomy

#### PATHOLOGICAL DISCUSSION

DR BENJAMIN CASTLEMAN. The preoperative diagnosis was acute pancreatitis. The surgeon found a large amount of bloody fluid in the abdomen and extensive induration of fat, especially along the lesser curvature of the stomach, with small nodules more suggestive of fat necrosis than carcinoma. The liver appeared normal. The spleen was twice the normal size to palpation, but it was not visualized. The gastroduodenal omentum was opened and the pancreas carefully palpated. It was enlarged and indurated throughout. The gall bladder seemed thick, but he did not believe that it was diseased. A cholecystostomy and a jejunostomy were done—the latter for feeding purposes.

A biopsy of one of the nodules that the surgeon thought might be fat necrosis turned out to be carcinoma, but we could not tell where the tumor was primary.

The patient died a few days later, and at autopsy we found the stomach fairly well fixed. On the lesser curvature and the posterior wall was a large mass that extended to the left, up to the hilus of the spleen. All the retroperitoneal nodes along the aorta and beneath the stomach were involved with tumor. On opening the stomach we found that the mass adherent to the posterior wall did not involve the mucosa and was entirely extrinsic. The mass proved to be the pancreas involved from head to tail with

The patient was tense and frequently nauseated but appeared to obtain considerable relief from hot baths so that he stopped vomiting and was able to drink water. On the third hospital day the skin and scleras were slightly jaundiced. A surgical consultant found a tender mass in the epigastrium, extending to both sides of the midline but slightly more to the left. The edges of the mass were indefinite, the whole mass was about 15 cm in diameter. Rectal examination was negative. On the same day the gastrointestinal series showed some thickening of the gastric folds, and there was evidence of pressure along the lesser curvature and the posterior wall. The duodenal loop was enlarged, the second portion was displaced to the right and showed evidence of somewhat lobulated compression from the region of the pancreas, which also displaced the third portion of the duodenum downward. There were several diverticula in the colon. The spleen was enlarged. There was considerable fluid in the left pleural cavity. Linear areas of atelectasis showed in both lower lobes of the lungs, and motion of both leaves of the diaphragm was slightly limited. On the following day the icteric index was 25, and the serum amylase was 78 units per 100 cc. Three hundred and fifty cc of opaque, amber fluid, which proved to be sterile, was removed from the left chest. The temperature remained normal.

An operation was performed on the fifth hospital day.

#### DIFFERENTIAL DIAGNOSIS

**DR PERRY CULVER** In discussing this case I shall start with certain features that stand out as signposts toward arriving at a diagnosis. The first is a mass in the upper abdomen, in the region of the pancreas, if we can believe what the x-ray examination appeared to show. Perhaps at this time we should view the films to see if my conception of this mass is true.

**DR STANLEY M WYMAN** The films of the chest show rather definite pleural effusion on the left. The left main bronchus is perhaps displaced slightly downward. One can see no definite defect in its lumen. There is some atelectasis at the right base, and the changes in the left are probably partially the result of considerable atelectasis in the left lower lobe. The heart shadow does not appear definitely abnormal. The most striking change in this patient's examination lies in the duodenal loop, which is displaced laterally in the second portion and manifests a fairly constant contour in this region. Two spot films of that area confirm this impression and show what appears to be a somewhat lobulated mass pressing into the lumen at this point. Downward displacement of the third portion of the duodenum is seen. The displacement of the stomach I cannot see on these films but it may have been seen by the fluoroscopist. The large spleen extends downward

to this point. I can see no evidence of actual bony destruction.

**DR CULVER** Can you see evidence of metastases anywhere in the lung to account for the fluid?

**DR WYMAN** No, simply fluid, without definite evidence of intrinsic disease except for atelectasis.

**DR CULVER** The discovery of this mass three days after the initial physical examination when no mass had been found makes one wonder if this tender mass in the midepigastrium appeared suddenly overnight.

The second salient point is the sudden appearance of jaundice. Since the mass is in the general region of the common bile duct, the possibility of obstruction of the duct is suggested.

The third point that one has to bring into the picture is the rather marked weight loss of 25 pounds in approximately six weeks. Apparently the patient had retained most of the ingested food until two days before admission, so that he did not lose the 25 pounds because of limited food intake or from vomiting.

The fourth point is the fluid in the left chest. These four facts have to be reconciled with what was apparently a consistently normal temperature, a normal white-cell count, and no anemia. We also have to try to fit the enlarged spleen into the picture.

When I read this abstract over, I immediately thought that the mass, the jaundice and the marked weight loss were the three salient points for carcinoma of the pancreas. One can add to such possibilities that of fluid in the left chest from metastasis to the pleura. Then, because of the sudden appearance of the mass in the midepigastrium, where no mass had been felt three days before, one could postulate that there was sudden development of a cyst of the pancreas. It is rather common for a cyst of the pancreas to develop on the basis of carcinoma. I would like to speculate that there had been a hemorrhage or bleeding into the cyst to account for its rapid increase in size. While carcinomas of the pancreas are statistically one of the common causes of painless jaundice, approximately 50 per cent of all carcinomas of the pancreas cause pain. Many cause back pain, which is most severe. Often an erroneous diagnosis of psychoneurosis is made because no one can explain the back pains until the diagnosis finally becomes evident post mortem.

If these were all the facts, the diagnosis would be easier, but we have to consider other things. What is the relation of his mental status to the symptomatology? The business and family worries gave this man a perfect background for peptic ulcer. The psychosomatic experts on duodenal ulcer say that people with the ulcer type of personality remain asymptomatic as long as either their business or their family life runs smoothly. When both are disturbed ulcers develop. This man had both things to plague him. The fact that he had a recurrence under stress also suggests an ulcer. In addition, the

ampy pains in the back suggest penetration of an ulcer in the pancreas. The tenderness in the epigastrium can again be caused by a penetrating ulcer. Many hold an opinion that tenderness does not occur with a duodenal ulcer until there is penetrating involvement of either the pancreas or peritoneal surface of the duodenum. So much for the ulcer. It will not explain such things as the fluid in the chest, the mass in the midepigastrium, and probably the jaundice.

What next? Gallstones should be considered. The patient had recurrent pains in the back and whenever one elicits this fact one must think of gallstones as well as peptic ulcer. Moreover, with this recurrent periodic pain there was associated nausea and vomiting. If jaundice appears, it is even more suggestive of gallstones obstructing the common duct. Unfortunately, there should have been fever and leukocytosis for the diagnosis of gallstones. Unless there were complications from the gallstones, he should not have had this mass in the midepigastrium and the fluid. One could suggest that the gallstone had perforated into the lesser omental cavity, and that the patient then developed an abscess of the lesser omental cavity. It could then cause inflammatory obstruction of the common duct and perhaps extension of fluid through the left leaf of the diaphragm. We might even consider that because of this mass the splenic vein had been involved with thrombosis and, ergo, a large spleen. It is a good story but we have no elevation of the white-cell count and no fever to go with it.

Another possibility is that a person with severe pain in this region and a mass, which might be a pancreatic cyst, could have chronic recurrent pancreatitis or acute pancreatitis. So far as acute pancreatitis is concerned, this man was sick enough but he did not have a high white-cell count, he did not have a high temperature, he had no board-like abdomen—in fact, nothing to go with acute pancreatitis except for the serum amylase of 78 units. In this hospital the serum amylase is so variable that we cannot put much emphasis on a single determination. If we had had another determination, either twelve or twenty-four hours before that, and if it had been approximately 30 units, or another twenty-four hours later and had it been around 125 to 150 units, we could say that the serum amylase was significant. This 78 units was an isolated reading. A determination of 50 or 55 units is considered the upper limit of normal. With an amylase of 78 units if we wanted to "go out on a limb," we could say that this man had pancreatitis. So we are left somewhat in a quandary.

I have covered the essentials of my differential diagnosis and I still have not considered one point, that is, the rambling speech and difficulty in recalling dates and time. I am frankly stumped as to how to explain these neurologic changes. It is possible that excessive electrolyte depletion due to the

vomiting was the basis for this neurologic manifestation. We know that some decompensated cardiac patients, who are treated intensively with salt restriction and dehydration, are "out in left field" because of hyponatremia.

I am sure I shall be wrong but I am going to say that he had carcinoma of the pancreas, with possible involvement of the splenic vein and thrombosis to explain the enlarged spleen, metastases to the left pleura to explain the fluid in the left chest and that he developed a cyst of the pancreas, secondary to the cancer.

#### CLINICAL DIAGNOSIS

Acute pancreatitis?

#### DR. CULVER'S DIAGNOSES

Carcinoma of pancreas

Pancreatic cyst.

Metastatic cancer of left pleura

Splenomegaly due to thrombosis of splenic vein

#### ANATOMICAL DIAGNOSES

*Carcinoma of pancreas, with extension to stomach, transverse colon, and spleen, with metastases to retroperitoneal lymph nodes, lungs and kidney*

Hydrothorax, bilateral

Pulmonary atelectasis, left lower

Operations: cholecystostomy and jejunostomy

#### PATHOLOGICAL DISCUSSION

DR. BENJAMIN CASTLEMAN: The preoperative diagnosis was acute pancreatitis. The surgeon found a large amount of bloody fluid in the abdomen and extensive induration of fat, especially along the lesser curvature of the stomach, with small nodules more suggestive of fat necrosis than carcinoma. The liver appeared normal. The spleen was twice the normal size to palpation, but it was not visualized. The gastrocolic omentum was opened and the pancreas carefully palpated. It was enlarged and indurated throughout. The gall bladder seemed thick, but he did not believe that it was diseased. A cholecystostomy and a jejunostomy were done—the latter for feeding purposes.

A biopsy of one of the nodules that the surgeon thought might be fat necrosis turned out to be carcinoma, but we could not tell where the tumor was primary.

The patient died a few days later, and at autopsy we found the stomach fairly well fixed. On the lesser curvature and the posterior wall was a large mass that extended to the left, up to the hilus of the spleen. All the retroperitoneal nodes along the aorta and beneath the stomach were involved with tumor. On opening the stomach we found that the mass adherent to the posterior wall did not involve the mucosa and was entirely extrinsic. The mass proved to be the pancreas involved from head to tail with

cancer The tumor had extended into the spleen and what was believed to be a large spleen was spleen plus tumor The tumor had also extended to the transverse colon and microscopically there were metastases to the lung and kidney The shadow in the left-lower lung field seen on the x-ray examination was 2 liters of clear fluid with compression atelectasis of the left lower lobe There was also a liter of fluid in the right pleural cavity An interesting incidental finding microscopically was an islet of Langerhans in the pancreas about five times the normal size It may have been a section through a small adenoma that was not recognized grossly because of the widespread carcinomatous invasion

Unfortunately we were not permitted to examine the brain, but it is not uncommon for patients with carcinoma of the pancreas to have mental symptoms without evidence of cerebral metastases Why, no one knows

A PHYSICIAN Was a blood sugar done?

DR CASTLEMAN No The urine did not contain any sugar

A PHYSICIAN How about the nonprotein nitrogen?

DR CASTLEMAN It was normal I believe that the elevated amylase can be explained by the extensive involvement of the pancreas by tumor

DR CULVER The more of these cases we see, the more I am impressed with how varied and bizarre the symptomatology can be I remember one case that I saw in consultation as a problem in vitamin deficiency because the patient had numbness and tingling of the toes He had been treated with larger and larger doses of vitamins without relief of his peripheral neuritis He also had pain in the back No one paid any attention to it When he died a year later a carcinoma of the pancreas was found at autopsy as the probable cause of the difficulty A great many of these people who have carcinoma of the pancreas are diagnosed as psychoneurotics for a period of time They have vague backaches, the x-ray films are normal, and they have all sorts of symptoms, but no one is able to fit them into any syndrome One should become sensitized to the possibility of carcinoma of the pancreas How to prove it is another story

DR CASTLEMAN It is interesting that the man who interpreted these x-ray films originally concluded "The findings are those of a mass in the region of the pancreas I would think that the entire pancreas was involved and although carcinoma cannot be definitely excluded, pancreatitis with involvement of the lesser omentum would be my first choice" That is what probably influenced the surgeon in making the preoperative diagnosis

DR CULVER Was the mass cystic or solid?

DR CASTLEMAN It was a very necrotic tumor

DR CULVER That is probably the reason it was tender

## CASE 34322

### PRESENTATION OF CASE

A thirty-seven-year-old Negro was admitted to the hospital complaining of progressive blindness, proptosis of the left eye and pain in the left supraorbital region

One month prior to entry he was admitted to another hospital with similar complaints of about one week's duration A note from that hospital concerning the patient reported that x-ray examination had revealed sinusitis X-ray studies of the skull were negative A spinal puncture revealed normal pressure and cell count, with a negative globulin reaction The gold-sol curve was 0000000000 The Wassermann reaction was positive A blood culture was negative Two weeks following admission to the other hospital an acute epididymitis developed and he was subsequently transferred to this hospital

On physical examination the patient was obviously acutely ill There were proptosis of the left eye and complete bilateral nasal obstruction, with a cheesy purulent material in the vestibules A left external ethmoid incision was present, and the sinuses were dark to transillumination The soft palate was pushed downward and forward, and the soft and hard palate were both swollen and indurated A Caldwell-Luc incision was present on the left side The chest and abdomen were negative The left testicle was enlarged to about the size of a small orange and did not transmit light Examination in the Eye Clinic revealed retention of ability to project light accurately in the right eye, with total blindness on the left Impairment of ability to move the eyes laterally and some loss of power to move the muscles supplied by the seventh nerve were also noted

The temperature was 103.4°F The blood pressure was 90 systolic, 60 diastolic

Examination of the blood showed a red-cell count of 3,680,000, with 11.8 gm of hemoglobin, and a white-cell count of 6300, with 75 per cent neutrophils The urine sediment contained 8 to 10 white cells per high-power field Spinal puncture revealed an initial pressure equivalent to 170 mm of water, with a total protein of 172 mg per 100 cc The sugar was 63 mg per 100 cc, and a cell count showed 480 white cells per cubic millimeter, with 39 per cent polymorphonuclears and 61 per cent lymphocytes A gold-sol curve was 0011233210 X-ray films of the chest were normal Those of the skull disclosed no enlargement of the sella turcica X-ray examination of the sinuses revealed that the cell partitions of the ethmoid sinuses were gone and all sinuses showed a soft-tissue density A large nasopharyngeal mass extended anteriorly into the nasal cavities All sinuses, including the sphenoid, were full Cultures from the nose, throat and left ethmoid showed *Staphylococcus aureus*

Following admission the patient's condition grew steadily worse, he became disoriented, and x-ray therapy was started. The patient improved somewhat for a short time but after about two weeks began to suffer from abdominal distention. He became steadily weaker and died after approximately one month in the hospital.

#### DIFFERENTIAL DIAGNOSIS

DR GRANTLEY W TAYLOR I am probably here because I know very little about tumors of the nose and throat and eye. This is fairly obviously a problem of neoplasm. It is worth while to make a few general remarks on the subject because I cannot go into the elaborate details of histology in these cases.

This thirty-seven-year-old man had a rather acute course. The first evidence of anything wrong, from his viewpoint, was progressive loss of vision and proptosis of the eye and pain in the superior orbital area that initially took him to another hospital, where, I presume, a diagnosis was made of chronic infection involving the accessory sinuses, probably primarily the ethmoid. We see this evidence of ethmoid disease in an occasional case, namely, disturbance of vision and proptosis of the eye and headache. It is consistent with a diagnosis of infection. However, the findings at the other hospital were not consistent with the diagnosis of infection primarily. He had a normal chart and a normal leukocyte count, and even if it was obvious that the disease was more in the nature of a chronic non-inflammatory process, the evolution was rapid after he entered the other hospital. He had two operations, one, we know, was an ethmoid operation, the scar of which was visible when he came here. The other was a Caldwell-Luc incision. By the time he arrived here there was no question that he had tumor of marked extent. The palate was pushed downward, the nares were obstructed, and there were blindness of the left eye and proptosis. Obviously he had a tumor mass originating in the general vicinity of the nasopharynx or the ethmoid area, with probable direct extension into the orbit and probable further extension through the orbital foramen into the base of the skull. When he came here he had a great deal of evidence of neurologic disturbance around the head and base of the skull, which could be interpreted not so much as due to pressure from the tumor as probably the result of direct invasion. He had no elevation of white-cell count but he had a temperature. He had a gold-sol curve and white cells

in the spinal fluid, and we must assume that he had a direct local meningitis due to progress of the tumor and introduction of infection through the base of the skull.

I should like to look at the x-ray films and have Dr Wyman point out the soft-tissue masses that are described. Interpretation of x-ray films of the sinuses is a highly specialized art.

DR STANLEY M WYMAN The soft-tissue thickening in the posterior nasopharynx is best seen in the lateral view and is confined chiefly to the roof of the nasopharynx in this area. There is soft-tissue density extending upward and obliterating the normal ridges of the sphenoid and wiping out completely the normal cell partitions in the ethmoid sinuses. With a strong light one can see soft tissue extending far forward into the posterior nares. There is probably some haziness in the frontal sinuses, although this is less definite. A frontal projection shows density in both ethmoid sinuses, with complete loss of the cell walls and probably some hazy density in the frontal sinuses. This position shows a soft-tissue density overlying the left orbit, a fairly definite mass extending upward where the left eye is being pushed forward. A view of the floor of the skull shows density in both ethmoid sinuses of rather uniform, hazy character, showing only a small airway far posteriorly. I can see no definite bone destruction, however.

DR TAYLOR We are confronted with a rapid evolution of a large tumor mass that fills the nasal passages, the nasopharynx and the accessory sinuses and that has destroyed bone, and it seems to me that the only conclusion one can derive is that we are dealing with a rapidly growing and highly malignant neoplasm. What is the nature of it? When this point is reached all one can say is that the answer is something the microscope alone can give. We have a number of rapidly growing and highly malignant tumors that may occur in this area. They may be primarily carcinoma, ordinarily either in the sinuses or in the pharynx, and there are also sarcomas seen in this area. Which of these we are dealing with in this case is largely a matter of guess. It is interesting that although there is no specific description of the neck, we can probably assume that there is nothing in the way of metastases to the regional lymph nodes. We know that these rapidly growing carcinomas in this general area are prone to form early bilateral cervical-lymph-node metastases. We have an x-ray examination of the

chest during the terminal illness, which showed no evidence of dispersion of the disease. Both these factors, I think, argue considerably against a carcinoma and in favor of a sarcoma. It is largely a matter for the pathologist to decide.

The clinician was confronted in this case with the problem of what to do about it. Quite obviously with disease as extensive as that described here in the physical examination and as revealed by x-ray study, the only hope was that we were dealing with a tumor highly sensitive to radiation. Accordingly, this method of treatment was undertaken, in spite of which there was no particular improvement. It seems to me that if this sarcoma, as I have said, was of the lymphocytic series, Hodgkin's disease or lymphoblastic type, there would probably have been an initial very gratifying and rapid response. Such does not seem to have been the case. It seems, therefore, more reasonable to say that this is perhaps a sarcoma of the neurogenic group — a neurofibrosarcoma or a glioma or one of those tumors.

I cannot go very much farther than that, Dr Mallory. The lesson, I think, is that when anybody has a bizarre cold with sinus infection that does not respond to ordinary, reasonable measures, the possibility of a diagnosis of neoplasm should be entertained. The more we look for this the more likely we are to find it at an early stage. In this case even if the diagnosis had been made initially, the man's "goose was cooked."

DR TRACY B MALLORY: I think the abstract is misleading. There is a note to the effect that the local tumor had responded fairly well to radiation, but two days later the patient died.

DR TAYLOR: I still will be glad to hear what you found.

A PHYSICIAN: How about the possibility of tumor primary in the testicle with metastasis to the brain, such as a chorioepithelioma?

DR TAYLOR: It is nice of you to bring it up. I wondered if we should discuss the possibility of metastatic carcinoma. It is highly unlikely. We have, in a few cases, seen that occur — localized metastatic neoplasm. I did not consider this necessarily a tumor of the testis, even though it did not transmit light. He had an acute epididymitis two weeks after admission to the other hospital. In other words, we could say that the testicle was innocent at the time of the initial physical examination, when the disease in the nasopharynx was well along. That is the only physical finding other than the local

one that could be implicated. One could also say that he had a renal-cell carcinoma with a solitary metastasis and never showed anything in the kidney. That is also possible, but we would not be dealing with the facts as presented.

A PHYSICIAN: Can you rule out gumma in view of the positive Wassermann test?

DR TAYLOR: I gave some thought to gumma but was inclined to pay not a great deal of attention to it. I do not believe that a gumma would evolve so rapidly and give rise to such an extensive soft-tissue mass as he had. I am not expert enough in relation to the gold-sol test and that sort of thing to say that the gold-sol curve is not consistent with a syphilitic disease. But it seems to me that he suffered from probable pyogenic localized invasion of the meninges around the base of the brain, which accounted for some of the seventh-nerve weakness and the impaired ocular motor functions on the other side and so forth.

DR JOSEPH C AUB: I did not see this patient but I am intrigued by Dr Taylor's discussion of the metastases. Are not tumors in this area prone to go to the brain? Do you not believe that this was a metastasis to the brain?

DR TAYLOR: I would say direct extension rather than metastasis.

DR AUB: The x-ray therapy might well have been of influence.

DR TAYLOR: You mean on the ground that x-ray treatment might have made it worse?

DR AUB: Yes, it may have facilitated the spread of infection.

DR TAYLOR: He had this ethmoid trouble before x-ray treatment was started. As I read it I thought that the infection was already there. Whether x-ray therapy would facilitate the transmission of infection, I do not know.

DR WYMAN: It is quite consistent, as Dr Taylor said, with a malignant lesion in the posterior nasopharynx invading the sinuses, and from the point of view of x-ray therapy one can go no farther than to say that it is probably malignant neoplasm.

#### CLINICAL DIAGNOSIS

Malignant tumor involving nasal chambers, ethmoid and sphenoid sinuses, left lateral and anterior nasal walls, nasopharynx, hard and soft palate and left periorbital tissue.

## DR TAYLOR'S DIAGNOSIS

Sarcoma, type undetermined

## ANATOMICAL DIAGNOSES

*Malignant lymphoma (stem-cell type), with involvement of nasopharynx, air sinuses, left orbit, base of skull, retroperitoneum, left testicle, left kidney and pancreas*  
*Extradural abscess, right middle fossa*

## PATHOLOGICAL DISCUSSION

DR MALLORY A biopsy of this tumor was done before x-ray treatment was started. I did not consult Dr Taylor with that because our report on it was that the tumor was extremely variable in appearance. In some areas it suggested plasma-cell myeloma, in other areas neuroblastoma, and in still other areas lymphoblastoma. We were unable on the biopsy to make any diagnosis more specific than extremely malignant neoplasm.

At autopsy we found this large tumor mass involving the entire nasopharyngeal region and the sinuses. It had partially eroded and markedly thinned the bone at the base of the skull, particularly the wings of the sphenoid, and extended into the orbit and the nares. The blindness was due to a direct involvement of the optic nerve. We also found considerable tumor elsewhere in the body. The testis was involved with tumor and all the retroperitoneal tissues were a massive sheet of tumor. Tumor infiltration had obliterated all the retroperitoneal lymph nodes surrounding the aorta, had encapsulated both adrenal glands, invaded the kidneys at one spot, and surrounded and invaded the pancreas. The only suggestion of this extensive abdominal involvement in the physical examination was the vague description of distention of the

abdomen. There was enough tumor in the retroperitoneal tissues to explain the distention, and I imagine no isolated tumors could be felt.

From the histologic appearance of the tumor, the diagnosis is still, I think, a matter of some question. The distribution puzzled us quite a bit, it was essentially the distribution of lymphomatous tumor and the histology is consistent with that. We finally called it a reticulum-cell sarcoma of a very undifferentiated type. The possibility of plasma-cell myeloma was seriously considered at autopsy because the nasopharynx is the one spot in the body where plasma-cell myeloma or plasmacytomas are common outside the bone marrow. There was, incidentally, diffuse involvement of the bone marrow with multiple small foci of tumor.

DR TAYLOR He did not have an anemia so marked as to suggest that type of disease?

DR MALLORY The anemia may have progressed during his stay in the hospital. I think we have very little evidence on that. During all the early period in the first hospital, and even for several days in this hospital, this was considered to be an inflammatory process. The possibility of sinus thrombosis was seriously considered and the thought of neoplasm occurred a little bit later. There was secondary infection of the tumor and this infectious process had extended through the sphenoid and produced a localized, extradural abscess, but there was no true meningitis.

DR BERNARD M JACOBSON Was the spleen involved?

DR MALLORY No.

DR TAYLOR The superficial lymph nodes of the neck were entirely free?

DR MALLORY Yes.

## THE THYROID NODULE

MUCH of the recent literature concerning the thyroid gland has emphasized the conflicting opinions that exist regarding the incidence of carcinoma of this structure, and the interpretation of the nodule in the gland as precancerous. On the one hand reports from surgical clinics where an aggressive attitude is followed disclose that carcinoma is discovered in a large percentage of apparently innocent nodules, opposed to this are the analyses of routine autopsy material indicating a very low incidence of thyroid carcinoma as a cause of death. A further complication enters the picture with the disagreements among pathologists in interpretation of borderline conditions, adenomas with blood-vessel invasion, carcinoma in aberrant thyroid tissue and benign metastasizing goiter. The impartial observer is brought to the conclusion that a wide

disparity exists between histologic character and clinical behavior or, alternatively, that carcinoma of the thyroid gland is readily curable in the earliest stages, when the disease is not recognizable clinically.

Currently, evidence of cancer is found in about 20 per cent of the single nontoxic nodules that are removed surgically at the Massachusetts General Hospital. This high incidence of thyroid cancer may be contrasted with the experience at the Pondville Hospital, where only 46 cases have been encountered in twenty years, or approximately 1 case among every 300 cases of all types of cancer.

There is general agreement that the highest incidence of cancer is found in the single nontoxic adenoma, although all types of thyroid disease have been associated with carcinoma. At the Pondville Hospital more than 10 per cent of the thyroid carcinomas have arisen in toxic goiters.

The paper of Anglem and Bradford published elsewhere in this issue of the *Journal* offers further evidence of the incidence of carcinoma in thyroid nodules, and also sheds some light on the apparently low incidence in autopsy statistics. The study emphasizes the frequency with which carcinoma may be found in an apparently benign nodule. It seems probable that with the increasing employment of medical measures in the management of hyperthyroidism, the incidence of carcinoma in the remaining group submitted to surgery will increase. There is also the possibility that the drugs used in the treatment of hyperthyroidism may in some cases precipitate the development of carcinoma.

Regardless of the role of the nontoxic adenoma, whether it is precancerous or merely indistinguishable from cancer in its earliest stages, there is sufficient evidence to justify prompt surgical intervention in all cases with single nontoxic nodules. Carcinoma discovered at this early stage is curable in a high percentage of cases. The decision to keep such a lesion under observation, and to resort to surgery only when the lesion by rapid growth or fixation raises the probability of malignant degeneration, is a serious one and not in the best interests of the patient. Operation performed when the diagnosis of cancer is obvious results in fewer cures. With thyroid carcinomas as with those of other regions, prompt intervention is likely to be successful. The nature of the nodule should be decided in the laboratory, not on its future course in the neck of the patient.

## THE BOSTON EYE BANK

THE Boston Eye Bank, affiliated with the Eye-Bank for Sight Restoration, Incorporated, of New York City, has been in operation for the past year and a half. The wisdom and foresight of those responsible for its establishment are attested by the number of people who have benefited from corneal transplantation through its services.

Naturally, the dramatic element in corneal transplantation has great popular appeal, and this has been reflected by the gratifying interest demonstrated by the public and lay press in the activities of the Eye Bank. Numerous requests are received daily for donation forms bequeathing eyes. However, at present it is not practical to obtain eyes from other than patients dying in a hospital. It is precisely in this connection that the medical profession, including hospital administrators, can do much to ensure success of this worthy project. Literature is available for reception rooms in hospitals and doctors' offices explaining the noble aims and purpose of the Eye Bank. At the time that permission for post-mortem examination is sought, a proper appeal could well be made, for the eyes.

No exact figures are available regarding the number of blind persons throughout the country who could be aided. The best estimates have been placed at 10,000 to 15,000. Obviously, it will take time and many high-minded persons to provide a sufficient number of eyes to restore that most precious gift, sight, to these unfortunate victims.

If, for some reason, an eye is not suitable for corneal transplantation, it is used in research, particularly in problems that do not lend themselves to solution by the use of animal eyes. For example, studies of the vitreous and the possibilities of vitreous transplantation are currently the object of much research.

In its short span, The Boston Eye Bank has proved a most valuable ally in the fight against blindness. The future is contingent upon the continuing support of the general public and the medical profession.

---

## CHLOROMYCETIN

IN THE field of virus and rickettsial diseases the therapeutic results of the use of chemotherapeutic and antibiotic agents have not been comparable to those obtained in infections with bacterial agents.

However there is accumulating evidence of progress in this field.<sup>1</sup> The sulfonamides and penicillin have been shown to be active against certain viruses of the psittacosis-lymphogranuloma group. Certain rickettsias have proved susceptible to para-aminobenzoic acid, and therapy with this agent has given favorable results in some diseases caused by this group of agents. Streptomycin has also been found to have some rickettsiostatic effect in fertile hens' eggs and also in guinea pigs. Thus far no really effective agent has been found that affects the smaller viruses such as those responsible for the encephalitides and influenza.

Interest at the moment is focused on a new antibiotic, chloromycetin.<sup>2-8</sup> This agent has been obtained in crystalline form from cultures of a *Streptomyces* similar to the ones that produce streptothricin. It is particularly noteworthy in that a large portion of the weight of chloromycetin is in the form of nonionic chlorine. One of the chief drawbacks of chloromycetin is its low solubility in water, but it is soluble in many solvents that can be used clinically, including propylene glycol. It is highly stable in water over a wide range of reaction and resists boiling.

In vitro this agent appears to be effective in fairly small concentrations against a large range of gram-positive and gram-negative organisms, but moderately high concentrations are required for certain mycobacteria and for a few gram-negative bacilli. It is not effective against fungi, protozoa or rabbit syphilis, but at least one strain of *Borellia* is extremely sensitive. In vivo it has been shown to be markedly effective against various strains of rickettsias in mice and eggs. It has also been found effective against some strains of psittacosis in eggs and mice, but not against most other viruses. It appears to be inferior quantitatively to streptomycin in mice against many infections and does not seem to have any effect against pneumococcal infections.

One of the great virtues of chloromycetin is that it seems to be effective in mice and dogs when given by mouth. It appears to have relatively low toxicity and, from the results obtained in mice, to be effective even late in the disease. Clinical trials have been undertaken in the treatment of epidemic typhus and in scrub typhus.<sup>9-12</sup> The early results as judged from press reports seem to be favorable, and the details will be awaited with considerable interest.

There is reason to believe that other chemotherapeutic and antibiotic agents with similar or greater effects against many viral and rickettsial diseases will become available in the not too distant future and with those already available will tend to bring under control another large group of serious infections

### THROUGH THE LOOKING GLASS

THE lonely heart may find its mate in unfrequented byways, trees grow in Brooklyn, stars fell, of all places, on Alabama Romance emerges where one least expects it Thus, in the *Bulletin of the United States Army Medical Department*, among such subjects as "Venereal Disease Anxiety" and "The Suddenness with which the Bowel Can Fill with Gas," appears the title, "Veterinary Inspection of Oysters"

And we had thought that the Army, by now, was fully mechanized

The term "veterinary," we had been led to believe through all these years by Webster (Noah), is "of or pertaining to the art of healing or treating the injuries and diseases of domestic animals" If by any stretch of the imagination this category can be expanded to include marine or aquatic life we should certainly expect the first candidate for veterinary attention to be the sea horse (genus *Hippocampus*), and its picket lines to be serviced by the Marine Corps, or at least the Navy — or perhaps the whole purpose of the project is to provide occupation for veterans

That there may be some reason, however, for believing that the oyster leads a double life, rising

from the relatively inert existence of a marine bivalve mollusk to an amphibious plane on which it attains a considerable degree of mobility, we can quote no less an authority than the late Lew Carroll

Whether or not it was veterinary inspection that they were anticipating, oysters have apparently been known to behave in an extraordinary manner, according to the observations of this great naturalist

Four other Oysters followed them,  
And yet another four,  
And thick and fast they came at last,  
And more, and more, and more —  
All hopping through the frothy waves,  
And scrambling to the shore

The method of locomotion of the succulent bivalve (genus *Ostrea*) is also somewhat reminiscent of the method by which horseflesh gets from one place to another, or wherever it happens to be going

"It seems a shame," the Walrus said,  
"To play them such a trick.  
After we've brought them out so far,  
And made them trot so quick!"

Nor is this zeal for clinical oceanology confined to the Army Medical Department According to the report of a special commission investigating the edible shellfish of the Commonwealth of Massachusetts, "both natural and artificial propagation of soft shell clams is necessary and feasible, and there is great need of reclaiming a greater number of shellfish from areas determined to be contaminated"

It might be the better part of wisdom to decide once and for all that areas so resolutely bent on their own contamination should be abandoned altogether, at least for the purposes of raising shellfish

Further inquiry into the veterinary inspection of oysters, however, reveals that hydrogen ion concentration, not hoof and mouth disease, is the subject of investigation

### MASSACHUSETTS MEDICAL SOCIETY

#### INFORMATION FROM VETERANS ADMINISTRATION

##### CERTAIN FEES INCREASED

On April 19, 1948, the Massachusetts Medical Society renegotiated its contract with the Veterans Administration. This contract became effective July 1, 1948 and is similar in every way to the previous contract, except that certain fees have been increased, for example, the Veterans Administration will now pay \$3.00 for an office visit, instead of the previous maximum of \$2.50. The fee for specialist treatment, except neuropsychiatric treatment, has been increased from \$3.00 to \$5.00.

### \$6000 MAXIMUM PAYMENT

During the fiscal year 1948 which ended on June 30, many doctors' earnings from the Veterans Administration were very near the \$6000 maximum limit allowed by law. With the new increase in fees as described in the previous paragraph, these doctors run the risk of exceeding their \$6000 limitation, if they order the same amount of service during the coming fiscal year. They should, therefore, maintain a fairly accurate record of work accomplished each month. In order to insure that the \$6000 maximum will not be exceeded, the doctor should limit his veterans' practice to a total earning of \$500 per month.

Reimbursement for services rendered in excess of \$6000 per year cannot be made. The salary limitation is based upon earnings during the fiscal year, from July 1, to June 30, and not based upon the payments made.

### REFERRAL OF PATIENTS

Occasionally during the course of treating a veteran, a doctor finds it necessary to refer his patient to another doctor for consultation or laboratory work. Whenever this is necessary, the Veterans Administration should always be notified in advance. Unless the Veterans Administration is so notified, authorization cannot be given and the veteran may have to pay the consultation fee.

### INFORMATION PHONE FOR DOCTORS

Two telephones at the V A Regional Office have been set aside for the use of physicians phoning for information. Trained clerks will be on duty from 8 30 a m to 5 15 p m each Monday through Friday. Call LA 3-7500, extensions 751 and 752.

### TREATMENT PROCEDURE INAUGURATED IN MASSACHUSETTS NOW USED IN OTHER STATES

On July 1, 1947 a new form of treatment authorization and a simplified procedure was tried out in Massachusetts. The response and co-operation received from Massachusetts physicians has been very gratifying. The reduction in the amount of paper work required of each doctor has elicited many favorable comments and has enabled many doctors who formerly were unable to cope with the excessive amount of paper work to participate in the Veterans Care Program. The procedure has also resulted in a net saving of 4,697 clerical man-hours per month at the Boston Regional Office, or the equivalent of twenty-six full-time employees. This is an excellent illustration of co-operation and teamwork eliminating many of the irritating problems frequently encountered in the administration of a large scale program.

On the first of May, the new form and procedure was introduced in Rhode Island, Connecticut, New Hampshire and Vermont, where it also has been favorably received.

### INFORMATION FOR NEWLY DESIGNATED FEE BASIS PHYSICIANS

Within the past few months, over 2000 new fee basis physicians have been approved for appointment by the Massachusetts Medical Society, consequently it is felt that a brief outline of Veteran Administration treatment requirements are in order.

- 1 The Veterans Administration authorizes out-patient treatment only for disabilities that have been adjudicated as service connected.
- 2 Except in an emergency the veteran should be required to present the physician with an authorization from the Veterans Administration office, before treatment is begun. If emergency treatment is rendered to a veteran it should be reported to this office within fifteen days.
- 3 Authorizations are for one calendar month only. If the veteran requires treatment during the following month, authorization should be requested on the yellow third page of the treatment form.
- 4 The veteran should be treated only for the specific disability covered by the authorization.
- 5 All reports of treatment and completed invoices must be submitted no later than the fifteenth of the month following the month in which treatment was rendered.
- 6 If medicine is prescribed the prescription blanks that are part of the second or pink page must be used. The veteran may have the prescription filled by any druggist who is a

member of the Massachusetts Pharmaceutical Association. The druggist in turn will be reimbursed by the Veterans Administration, through the State Association.

7 Prescribe only for the service connected disability shown on the authorization and only during the treatment period.

8 When forwarding completed reports to this office, retain the upper portion of the yellow or third copy for your files.

9 To identify payments received, the number listed on the reverse side of the voucher form, which accompanies the check, should be compared with the large number appearing on the yellow copy of the treatment authorization, retained by the doctor, in the box headed Fiscal Symbols.

10 If a physician believes that the number of treatments authorized is not sufficient for the month, or if the number of treatments authorized is less than the number requested, this office should be advised, giving a summary of treatment to date and a plan of future treatment, together with prognosis. The doctors authorizing these cases seldom see the patient and must rely almost entirely upon the reports submitted by the contracting physician.

11 All forms must be prepared in ink, typewriter or indelible pencil.

12 All reports of treatment and invoices must be personally signed by the doctor.

VETERANS ADMINISTRATION  
REGIONAL OFFICE

17 Court Street  
Boston 8, Massachusetts

### DEATHS

LEDBURY — John W Ledbury, M D, of Uxbridge, died on February 20. He was in his seventy-third year.

Dr Ledbury received his degree from College of Physicians and Surgeons of Baltimore in 1905. He was an affiliate fellow of the American Medical Association.

His widow, a daughter and two grandsons survive.

STRONG — Richard P Strong, M D, of Boston, died on July 4. He was in his seventy-sixth year.

Dr Strong received his degree from Johns Hopkins University School of Medicine in 1897. He was professor of tropical medicine, emeritus, at Harvard Medical School and was a member of the Association of American Physicians and a fellow of the American Medical Association.

A sister survives.

## MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

### RHEUMATIC FEVER FELLOWSHIPS

The United States Children's Bureau has made available through the Massachusetts Department of Public Health and the Harvard Medical School two fellowships in Rheumatic Fever at the House of the Good Samaritan of the Children's Medical Center, Boston, for the year beginning July 1, 1948.

Trainees should be interested in working eventually in the field of rheumatic fever in public health or in teaching, rather than in private practice.

Work under these fellowships will probably be acceptable for credit by the Board of Internal Medicine or the Board of Pediatrics.

Application should be made to Dr Benedict F Massell at the House of the Good Samaritan, 25 Binney Street, Boston 15, or BE 2-3002.

## MISCELLANY

### AMERICAN COLLEGE OF CHEST PHYSICIANS

Dr Richard H Overholt, of Brookline, took office as president of the American College of Chest Physicians at the fourteenth annual meeting of the College, June 17-20

## CORRESPONDENCE

### MORE ON ADOPTION

To the Editor I am delighted to see the editorial in the *Journal* of June 17 commending the work of the Boston Children's Friend Society on adoption and so indicating the importance of more and more care in this matter

The New England Home for Little Wanderers has been receiving into custody and placing children for adoption since 1865. With the passing of the years we have become more and more conscious of the importance of great care in procedure. We are sure that physicians, public-health officers and hospitals with whom we have co-operated have realized the protection we can give both children and family in the adoption process. Our staff is equipped with pediatrician, psychologist and psychiatrist, as well as with social workers, to assure a thoroughgoing service. During the past twelve months we have placed with a view to adoption 24 children and have completed the adoption of 35 children who had been placed for a year or more. We are acquainted with many fine young men and women who were placed for adoption as long as twenty-five or thirty years ago. Our experience confirms your statement "Few decisions require more tact and skill than the suitable placing of a child unwanted under one roof, so badly wanted under another."

CHENEY C JONES  
Superintendent

New England Home for Little Wanderers  
Boston, Massachusetts

## BOOK REVIEWS

*Stethoscopic Heart Records*. By George D Geckeler, M D. An album of four double-faced twelve-inch phonograph records. New York: Columbia Records, Incorporated, 1948. \$8.00.

While a book of records does not suggest the type of literature that is customarily reviewed in medical journals or elsewhere, stranger things are taking place in our brave new world where the electric impulse is used to convey both visual and auditory sensations, and the printed word may yet become the archaic symbol of another forgotten civilization.

This new issue of *Stethoscopic Heart Records*, ably presented by Dr Geckeler, provides a most satisfactory reproduction of a wide range of heart sounds, both normal and abnormal, including the arrhythmias and a variety of commonly encountered murmurs.

Although they are intended primarily for the practicing physician who wishes to keep his stethoscope ear in practice, these recordings will fill a variety of academic needs as well.

*Human Gastric Function. An experimental study of a man and his stomach*. By Stewart Wolf, M D, and Harold G Wolff, M D. With a foreword by Walter B Cannon, M D. Oxford Medical Publications. 8°, cloth, 262 pp., with 55 illustrations. New York: Oxford University Press, 1947. \$5.00.

The first and second editions of this book are continuations of the studies begun by Beaumont one hundred years ago on Alexis St. Martin, through a gastric fistula, on digestion in the stomach, the composition of gastric juice and the contraction and emptying of the stomach, but are far more complete and easy to read than Beaumont's "Observations on the Effects of the Mind on the Secretions of the Stomach and the Effect of the Mind on the Secretions of the Stomach and the Effect of the Mind on the Secretions of the Stomach."

Great care and skill and ingenuity have been shown in this study. The changes in appearance of the gastric mucus in severe emotion, the great increase in gastric secretions when the patient was worried, excited or obstinate, the rate of emptying of the stomach and the rapidity with which these changes came and went are described in a clear, simple and convincing way.

The influence of many agents—foods, drugs, coffee, tobacco, alcohol, acids, antacids, atropine, nitrites, histamine, epinephrine, methylcholine, prostigmin, pitressin, benadryl, emetics and others that have been used to change the gastric function—are critically examined, and it is shown that their action on the stomach may be modified or reversed by the effect of the mental state present at the time, previous data about the length of time food remains in the stomach must be revalued in the light of the great changes that occur in emotional states. It is interesting that no effect from tobacco smoking on the motor activity, acid secretion or vascularity of the stomach was formed in the patient unless nausea appeared.

The wide range of the appearance of the healthy gastric mucosa is important in relation to the diagnosis of gastritis. The authors found the difference between hyperfunction of the stomach, however caused, and hypertrophic gastritis mainly one of degree. The protective action of gastric mucus is well shown. Some valuable and fundamental applications of this research are made in the treatment of gastritis and ulcer.

Three chapters have been added to the first edition of 1943, including further data on the effects of chemical agents and other influences on gastric function and the gastric mucosa, further correlation of gastric function with life situations (causing depression, resentment, anger, worry, fear, frustration and so forth) and a timely chapter on gastric studies of a patient with fistula both before and after vagotomy.

The book is very interesting, and no internist, practitioner or psychologist can afford to miss it. It ranks as a medical classic, and its significance has already been widely recognized.

## BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

*Minor Surgery*. By Frederick Christopher, M D, associate professor of surgery, Northwestern University Medical School, and chief surgeon, Evanston (Illinois) Hospital. Sixth edition. 8°, cloth, 1058 pp., with 937 illustrations. Philadelphia: W B Saunders Company, 1948. \$12.00.

This standard textbook, first published in 1929 and last revised in 1944, has been again thoroughly revised, and many sections have been entirely rewritten and new sections added. The material on the use of penicillin and other antibiotics and the sulfonamides has been thoroughly revised in the light of present-day usage. The sections on thrombophlebitis and phlebotrombosis have been extensively revised and include consideration of anticoagulant therapy and femoral-vein ligation in the prophylactic treatment of pulmonary embolism. The sections on burns and varicose veins, pilonidal sinus, and methods of artificial respiration have been revised in the light of the knowledge gained from World War II. New material includes the control of hemorrhage by the gelatin sponge, or oxidized cellulose, early postoperative ambulation, Lund table of skull areas, procaine and serum sickness, plastic cast in burns, lumbar sympathetic block in thrombophlebitis, intra-arterial injection of penicillin and infections of the extremities, excision and encasement of bedsores, treatment of malignant melanoma, prosthetic restoration of amputate, finger, refrigeration anesthesia and the use of aluminum hydroxide paste in bowel fistula. The following sections have been amplified: wound healing, diet and burns, injection of novocain, and subacromial bursitis, Colles fracture, fracture of the carpal scaphoid, glomus tumors, novocain injection for ankle sprains, march fractures, sternal puncture, the

iting, the Rh factor, shock, fluid and electrolyte administration after operation, hypoproteinemia, use of the Miller-bott tube and pulmonary atelectasis. A selected bibliography is appended to each chapter, and a good index condenses the volume. The work is well published in every way and is recommended for all medical libraries and should prove of value to all persons interested in surgery.

*Sulfonamides and Allied Compounds*. By Elmore H. Orthner, Ph.D., administrative director, Stamford Research Laboratories, American Cyanamid Company, Stamford, Connecticut. 8°, cloth, 660 pp., with 323 tables. New York: Reinhold Publishing Corporation, 1948. \$12.50.

This essential reference work covers the chemical side of the sulfonamide derivatives, simple and complex, the sulfones and their derivatives and other allied compounds. The structure and activities of the compounds are considered extensively. There are special chapters on the experimental evaluation and relation to structure of chemotherapeutic activity, pharmacology, theories of the mechanism of action and the clinical action of the drugs. In this fast expanding field over 300 new compounds have been synthesized, and in 1943 the United States produced over 10,000,000 pounds of sulfonamides. The first two chapters deal briefly with the history of antetarial chemotherapy and nomenclature, classification and synthesis. A comprehensive bibliography of 2668 references concludes the text. The appendices give a key of organisms and diseases, and the trade names for sulfanilamide, its derivatives and related compounds. The volume is well published in every way and is recommended for all medical libraries and to all physicians interested in chemotherapy.

*A Manual of Pharmacology and Its Applications to Therapeutics and Toxicology*. By Torald Sollman, M.D. Seventh edition. 4°, cloth, 1132 pp. Philadelphia: W. B. Saunders Company, 1948. \$11.50.

This standard work on pharmacology, first published in 1917, has been thoroughly revised to bring it up to date. In this revision the author has eliminated material no longer considered of real importance or interest. The text is printed in two columns and in two sizes of type. The large type presents material that should be known by all students, and the small type contains data for reference purposes. Since the publication of the last edition in 1942, there have been great advances in the field of pharmacology. Much material has been added throughout the volume, including the new antibiotic agents, the anti-infective sulfonamides, antimalarials, the antitumoral drugs, the insecticides and rodenticides, the toxins and weed killers. The antithyroids, anticonvulsants, antihistamines, anticholine acetylases, folic acids, standardized curare, digitoxin, nitrogen mustards and B.A.L. are considered in the text. The extensive bibliography of 112 pages appended to the text comprises references to the pertinent literature published since January 1, 1926. The volume is well published and is recommended for all medical libraries and as a reference work for physicians.

*The Industrial Environment and Its Control*. By J. M. Dallavalle. 8°, cloth, 225 pp. New York: Pitman Publishing Corporation, 1948. \$4.50.

This monograph in a new field of public health is well written, and the material well organized. Although technical in parts the text is kept as simple as possible and understandable to the average person. The monograph deals with engineering methods for the control of health hazards in factories. The first chapter discusses problems and trends, including the importance of industrial hygiene to the industrial physician and public-health administrator and the need for adequate reporting of morbidity and mortality. The various chapters consider psychrometry (the relation between temperature and humidity), air and its contamination, illumination and radiant energy, noise, vibration and fatigue, industrial ventilation in all its aspects, and industrial dust collection. An appendix discusses the general principles of industrial sanitation. Each chapter is documented with a list of pertinent references. The monograph is recommended for all public-health collections in medical and general libraries, in industrial plants and in health-department libraries of estates and cities, and to all persons interested in industrial sanitation. The printing is well done with a good type on good paper.

*Hernia: Anatomy, etiology, symptoms, diagnosis, differential diagnosis, prognosis and treatment*. By Leigh F. Watson, M.D. Third edition. 8°, cloth, 732 pp., with 323 illustrations. St. Louis: The C. V. Mosby Company, 1948. \$13.50.

This authoritative work, first published in 1924, has been thoroughly revised in the third edition, and the type entirely reset. Chapters have been added on the complications of hernia, internal supravescical and epigastric hernias, hernia into the broad ligament, recurrent inguinal hernia and industrial hernia. Cooper's ligament operation, Babcock's operation for inguinal hernia using stainless steel wire and Harrington's operation for diaphragmatic hernia are described and illustrated in detail. Material has also been added on early rising after operation, suture materials, embolism and thrombosis, preoperative and postoperative treatment and new statistics on the rarer types of hernia. Much space has been devoted to a thorough consideration of nonoperative treatment by the injection method, including its use in inguinal, femoral, umbilical epigastric and ventral hernias. The bibliography has been brought up to date and appended to each chapter. Comprehensive indexes of authors and subjects conclude the volume. Many illustrations have been added. The printing is well done with a good large type on good coated paper. This paper is probably necessary to ensure adequate reproduction of the fine illustrations, but it makes the volume rather heavy to handle. The book is recommended as an essential reference work for all medical libraries and to all surgeons.

*The Case Book of a Medical Psychologist*. By Charles Berg, M.D. (Lond.), D.P.M., fellow of the British Psychological Association, physician at the British Hospital for Functional Mental and Nervous Disorders and physician to the Institute for the Scientific Treatment of Delinquency. 8°, cloth, 260 pp. New York: W. W. Norton and Company, Incorporated, 1948. \$3.50.

Dr. Berg, in this second edition of his case book, has made a few minor changes and has substituted a long analytical case report for the three last articles in the section on war neuroses. All the papers were published originally in medical and psychologic periodicals. The text is written in a semi-popular style and presents 34 cases, illustrative of the practical application of clinical psychology. Four cases of war neuroses are included for the purpose of demonstrating that these cases do not differ in any essential particular, except the ease of curability, from the average case treated by the clinical psychologist. The theoretical explanations attached to each case have been reduced to a minimum, but enough has been included to interest the general reader and prove of value to the practitioner of clinical psychology. In the last chapter the author discusses the theory and practice of psychoanalysis. The book is well published and should prove of value to all physicians interested in nervous and mental diseases.

*Operative Gynecology*. By Harry S. Crossen, M.D., consulting gynecologist to the Barnes Hospital, St. Louis Maternity Hospital, St. Luke's Hospital, de Paul Hospital and Jewish Hospital, and Robert J. Crossen, M.D., assistant professor of clinical gynecology and obstetrics, Washington University School of Medicine, assistant gynecologist and obstetrician to the Barnes Hospital and the St. Louis Maternity Hospital and gynecologist to St. Luke's Hospital and de Paul Hospital. Sixth edition. 4°, cloth, 999 pp., with 1534 illustrations. St. Louis: The C. V. Mosby Company, 1948. \$15.00.

The first edition of this standard textbook was published in 1915, and the last edition in 1938. This new edition has been revised to bring it up to date, and to accommodate the large number of new data it was necessary to eliminate much of the historical material. This will make it essential for libraries interested in medical history to retain the fifth edition (1938) in their collections. Included in the new material are measures for the prevention of cancer, made a part of the sections on the various organs, and the development of measures for giving more effective relief to patients with general handicaps contraindicating operative removal of serious pelvic lesions. The volume is well published in every way. The many fine illustrations necessitate the use of a heavy paper, a fact to be deplored. The book is recommended for all medical libraries and should be in the collections of all gynecologists.

## MISCELLANY

### AMERICAN COLLEGE OF CHEST PHYSICIANS

Dr Richard H. Overholt, of Brookline, took office as president of the American College of Chest Physicians at the fourteenth annual meeting of the College, June 17-20

## CORRESPONDENCE

### MORE ON ADOPTION

To the Editor: I am delighted to see the editorial in the *Journal* of June 17 commending the work of the Boston Children's Friend Society on adoption and so indicating the importance of more and more care in this matter.

The New England Home for Little Wanderers has been receiving into custody and placing children for adoption since 1865. With the passing of the years we have become more and more conscious of the importance of great care in procedure. We are sure that physicians, public-health officers and hospitals with whom we have co-operated have realized the protection we can give both children and family in the adoption process. Our staff is equipped with pediatrician, psychologist and psychiatrist, as well as with social workers, to assure a thoroughgoing service. During the past twelve months we have placed with a view to adoption 24 children and have completed the adoption of 35 children who had been placed for a year or more. We are acquainted with many fine young men and women who were placed for adoption as long as twenty-five or thirty years ago. Our experience confirms your statement: "Few decisions require more tact and skill than the suitable placing of a child unwanted under one roof, so badly wanted under another."

CHENEY C. JONES  
Superintendent

New England Home for Little Wanderers  
Boston, Massachusetts

## BOOK REVIEWS

*Stethoscopic Heart Records*. By George D. Geckeler, M.D. An album of four double-faced twelve-inch phonograph records. New York: Columbia Records, Incorporated, 1948. \$8.00.

While a book of records does not suggest the type of literature that is customarily reviewed in medical journals or elsewhere, stranger things are taking place in our brave new world where the electric impulse is used to convey both visual and auditory sensations, and the printed word may yet become the archaic symbol of another forgotten civilization.

This new issue of *Stethoscopic Heart Records*, ably presented by Dr. Geckeler, provides a most satisfactory reproduction of a wide range of heart sounds, both normal and abnormal, including the arrhythmias and a variety of commonly encountered murmurs.

Although they are intended primarily for the practicing physician who wishes to keep his stethoscope ear in practice, these recordings will fill a variety of academic needs as well.

*Human Gastric Function. An experimental study of a man and his stomach*. By Stewart Wolf, M.D., and Harold G. Wolff, M.D. With a foreword by Walter B. Cannon, M.D. Oxford Medical Publications. 8°, cloth, 262 pp., with 55 illustrations. New York: Oxford University Press, 1947. \$5.00.

The first and second editions of this book are continuations of the studies begun by Beaumont one hundred years ago on Alexis St. Martin, through a gastric fistula, on digestion in the stomach, the composition of gastric juice and the contractions and emptying of the stomach, but are far more complete and interesting and easy to read than Beaumont's "Observations and Experiments" and more useful at present, when men are interested in the causes of ulcer and gastritis, the reasons for their recurrence and the effect of the mind on the stomach.

Great care and skill and ingenuity have been shown in this study. The changes in appearance of the gastric mucosa in severe emotion, the great increase in gastric secretion when the patient was worried, excited or obstinate, the rate of emptying of the stomach and the rapidity with which these changes came and went are described in a clear, simple and convincing way.

The influence of many agents—foods, drugs, tobacco, alcohol, acids, antacids, atropine, nitrates, histamine, epinephrine, methylcholine, prostigmin, pituitrin, benadryl, emetics and others that have been used to change the gastric function—are critically examined, and it is shown that their action on the stomach may be modified or reversed by the effect of the mental state present at the time, previous data about the length of time food remains in the stomach must be revalued in the light of the changes that occur in emotional states. It is interesting that no effect from tobacco smoking on the motor activity, acid secretion or vascularity of the stomach was found in the patient unless nausea appeared.

The wide range of the appearance of the healthy gastric mucosa is important in relation to the diagnosis of gastritis. The authors found the difference between hyperfunction of the stomach, however caused, and hypertrophic gastritis mainly one of degree. The protective action of gastric mucus is well shown. Some valuable and far-reaching mental applications of this research are made in the treatment of gastritis and ulcer.

Three chapters have been added to the first edition of 1943, including further data on the effects of chemical agents and other influences on gastric function and the gastric mucosa, further correlation of gastric function with emotional situations (causing depression, resentment, anger, worry, fear, frustration and so forth) and a timely chapter on gastric studies of a patient with fistula both before and after vagotomy.

The book is very interesting, and no internist, practitioner or psychologist can afford to miss it. It ranks as a medical classic, and its significance has already been widely recognized.

## BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

*Minor Surgery*. By Frederick Christopher, M.D., associate professor of surgery, Northwestern University Medical School, and chief surgeon, Evanston (Illinois) Hospital. Sixth edition. 8°, cloth, 1058 pp., with 937 illustrations. Philadelphia: W. B. Saunders Company, 1948. \$12.00.

This standard textbook, first published in 1929 and last revised in 1944, has been again thoroughly revised, and many sections have been entirely rewritten and new sections added. The material on the use of penicillin and other biotics and of the sulfonamides has been thoroughly revised in the light of present-day usage. The sections on thrombophlebitis and phlebothrombosis have been extensively revised and include a consideration of anticoagulant therapy and femoral-vein ligation in the prophylactic treatment of pulmonary embolism. The sections on burns and varicose veins, pilonidal sinuses and methods of artificial respiration have been revised in the light of the knowledge gained from World War II. New material includes the control of hemorrhage by the gelatin sponge, oxidized cellulose, early postoperative ambulation, Lund's table of skin areas, procaine and serum sickness in thrombophlebitis, in burns, lumbar sympathetic block in thrombophlebitis, intra-arterial injection of penicillin and infections of the extremities, excision and enclosure of bedsores, treatment of malignant melanoma, prosthetic restoration of amputated finger, refrigeration anesthesia and the use of aluminum hydroxide paste in bowel fistula. The following sections have been amplified: wound healing, diet and burns, injection of novocain, and subacromial bursitis, Colles fracture, fractures of the carpal scaphoid, glomus tumors, novocain injections for ankle sprains, march fractures, sternal puncture, skin

ing, the Rh factor, shock, fluid and electrolyte administration after operation, hypoproteinemia, use of the Miller-Ritt tube and pulmonary atelectasis. A selected bibliography is appended to each chapter, and a good index concludes the volume. The work is well published in every way and is recommended for all medical libraries and should prove valuable to all persons interested in surgery.

*Sulfonamides and Allied Compounds*. By Elmore H. Thyer, Ph.D., administrative director, Stamford Research Laboratories, American Cyanamid Company, Stamford, Connecticut. 8°, cloth, 660 pp., with 323 tables. New York: Knol Publishing Corporation, 1948. \$12.50.

This essential reference work covers the chemical side of the sulfonamide derivatives, simple and complex, the sulfones and their derivatives and other allied compounds. The structure and activities of the compounds are considered extensively. There are special chapters on the experimental evaluation and relation to structure of chemotherapeutic activity, pharmacology, theories of the mechanism of action and the clinical action of the drugs. In this fast expanding field over 30 new compounds have been synthesized, and in 1945 the United States produced over 10,000,000 pounds of sulfonamides. The first two chapters deal briefly with the history of sulfonamide chemotherapy and nomenclature, classification and synthesis. A comprehensive bibliography of 2668 references concludes the text. The appendixes give a list of organisms and diseases, and the trade names for sulfanilamide, its derivatives and related compounds. The volume is well published in every way and is recommended for all medical libraries and to all physicians interested in chemotherapy.

*Manual of Pharmacology and Its Applications to Therapeutics and Toxicology*. By Torald Sollman, M.D. Seventh edition. 4°, cloth, 1132 pp. Philadelphia: W. B. Saunders Company, 1948. \$11.50.

This standard work on pharmacology, first published in 1917, has been thoroughly revised to bring it up to date. In this revision the author has eliminated material no longer considered of real importance or interest. The text is printed in two columns and in two sizes of type. The large type presents material that should be known by all students, and the small type contains data for reference purposes. Since the publication of the last edition in 1942, there have been great advances in the field of pharmacology. Much material has been added throughout the volume, including the new antiparasitic agents, the anti-infective sulfonamides, antimalarials, the antitumor drugs, the insecticides and rodenticides, the anxiants and weed killers. The antithyroids, anticonvulsants, antihistamines, anticholinergic acetals, folic acids, standardized curare, digitoxin, nitrogen mustards and BAL are considered in the text. The extensive bibliography of 112 pages appended to the text comprises references to the pertinent literature published since January 1, 1926. The volume is well published and is recommended for all medical libraries and as a reference work for physicians.

*The Industrial Environment and Its Control*. By J. M. Dallavalle. 8°, cloth, 225 pp. New York: Pitman Publishing Corporation, 1948. \$4.50.

This monograph in a new field of public health is well written, and the material well organized. Although technical in parts the text is kept as simple as possible and understandable to the average person. The monograph deals with engineering methods for the control of health hazards in factories. The first chapter discusses problems and trends, including the importance of industrial hygiene to the industrial physician and public-health administrator and the need for adequate reporting of morbidity and mortality. The various chapters consider psychrometry (the relation between temperature and humidity), air and its contamination, illumination and radiant energy, noise, vibration and fatigue, industrial ventilation in all its aspects, and industrial dust collection. An appendix discusses the general principles of industrial sanitation. Each chapter is documented with a list of pertinent references. The monograph is recommended for all public-health collections in medical and general libraries, in industrial plants and in health-department libraries of estates and cities, and to all persons interested in industrial sanitation. The printing is well done with a good type on good paper.

*Hernia: Anatomy, etiology, symptoms, diagnosis, differential diagnosis, prognosis and treatment*. By Leigh F. Watson, M.D. Third edition. 8°, cloth, 732 pp., with 523 illustrations. St. Louis: The C. V. Mosby Company, 1948. \$15.50.

This authoritative work, first published in 1924, has been thoroughly revised in the third edition, and the type entirely reset. Chapters have been added on the complications of hernia, internal supravesical and epigastric hernias, hernia into the broad ligament, recurrent inguinal hernia and industrial hernia. Cooper's ligament operation, Bahcock's operation for inguinal hernia using stainless steel wire and Harrington's operation for diaphragmatic hernia are described and illustrated in detail. Material has also been added on early rising after operation, suture materials, embolism and thrombosis, preoperative and postoperative treatment and new statistics on the rarer types of hernia. Much space has been devoted to a thorough consideration of nonoperative treatment by the injection method, including its use in inguinal, femoral, umbilical epigastric and ventral hernias. The bibliography has been brought up to date and appended to each chapter. Comprehensive indexes of authors and subjects conclude the volume. Many illustrations have been added. The printing is well done with a good large type on good coated paper. This paper is probably necessary to ensure adequate reproduction of the fine illustrations, but it makes the volume rather heavy to handle. The book is recommended as an essential reference work for all medical libraries and to all surgeons.

*The Case Book of a Medical Psychologist*. By Charles Berg, M.D. (London), D.P.M., fellow of the British Psychological Association, physician of the British Hospital for Functional Mental and Nervous Disorders and physician to the Institute for the Scientific Treatment of Delinquency. 8°, cloth, 260 pp. New York: W. W. Norton and Company, Incorporated, 1948. \$3.50.

Dr. Berg, in this second edition of his case book, has made a few minor changes and has substituted a long analytical case report for the three last articles in the section on war neuroses. All the papers were published originally in medical and psychology periodicals. The text is written in a semi-popular style and presents 34 cases, illustrative of the practical application of clinical psychology. Four cases of war neuroses are included for the purpose of demonstrating that these cases do not differ in any essential particular, except the ease of curability, from the average case treated by the clinical psychologist. The theoretical explanations attached to each case have been reduced to a minimum, but enough has been included to interest the general reader and prove of value to the practitioner of clinical psychology. In the last chapter the author discusses the theory and practice of psychoanalysis. The book is well published and should prove of value to all physicians interested in nervous and mental diseases.

*Operative Gynecology*. By Harry S. Crossen, M.D., consulting gynecologist to the Barnes Hospital, St. Louis Maternity Hospital, St. Luke's Hospital, de Paul Hospital and Jewish Hospital, and Robert J. Crossen, M.D., assistant professor of clinical gynecology and obstetrics, Washington University School of Medicine, assistant gynecologist and obstetrician to the Barnes Hospital and the St. Louis Maternity Hospital and gynecologist to St. Luke's Hospital and de Paul Hospital. Sixth edition. 4°, cloth, 999 pp., with 1354 illustrations. St. Louis: The C. V. Mosby Company, 1948. \$15.00.

The first edition of this standard textbook was published in 1915, and the last edition in 1938. This new edition has been revised to bring it up to date, and to accommodate the large number of new data it was necessary to eliminate much of the historical material. This will make it essential for libraries interested in medical history to retain the fifth edition (1938) in their collections. Included in the new material are measures for the prevention of cancer, made a part of the sections on the various organs, and the development of measures for giving more effective relief to patients with general handicaps contraindicating operative removal of serious pelvic lesions. The volume is well published in every way. The many fine illustrations necessitate the use of a heavy paper a fact to be deplored. The book is recommended for all medical libraries and should be in the collections of all gynecologists.

**Modern Cosmetology** By Ralph G. Harry, F.R.I.C., certificate of the Royal Institute of Chemistry in the Chemistry and Microscopy of Foods, Drugs and Waters, Pharmacognosy, Pharmacology and Therapeutics, and head of the Cosmetic Department, Beecham Research Laboratories, Ltd. With a foreword by P. B. Mumford, M.D., F.R.C.P. Third revised edition 8°, cloth, 515 pp., illustrated. Brooklyn, New York: Chemical Publishing Company, Incorporated, 1947. \$12.00.

This third edition of an unusual book has been enlarged and completely revised. The work deals with the practical and scientific aspects of cosmetic preparations and includes special investigations by the author and others in this field. In addition to skin preparations there is included material on dental, hair, nail and eye preparations. The sections on skin nutrition, sunburn and sun-tan preparations, allergy and dermatitis, histology and physiology of the nails and hair, diet and skin health should prove valuable to physicians. There are hundreds of formulas for the preparations described in the text, making the book invaluable to the dermatologist. The text is documented throughout with pertinent references. A good index concludes the work. The material is well organized, and the text well written in a simple, clear style. The type and printing are excellent. The heavy coated paper could have been dispensed with, since the few plates are inserts. The book is recommended for all medical and general libraries, and as a reference work for dermatologists and physicians.

**Treatment by Diet** By Clifford J. Barborka, M.S., M.D., D.Sc., F.A.C.P., assistant professor of medicine, Northwestern University Medical School, attending physician, Passavant Memorial Hospital, and consultant in gastroenterology and gastroscopy, Diagnostic Centre, Hines Veterans Hospital. Fifth edition 4°, cloth, 784 pp., with 14 plates. Philadelphia: J. B. Lippincott Company, 1948. \$10.00.

This standard work, first published in 1934, and last revised in 1939, has been again brought up to date. More than half the volume has been rewritten, expanded or revised. Chapters on protein and amino acids, deficiency diseases, diet and skin diseases and on preoperative and postoperative dietary care have been added. New material on folic acid and on fat-soluble and water-soluble vitamins has been incorporated in the text. The chapter on liver disease has been rewritten to include the up-to-date use of protein, choline and other food factors in cirrhosis, chronic hepatic diseases and hepatocellular jaundice. In the chapter on diabetes mellitus the low carbohydrate diets have been eliminated and replaced by diets allowing up to 250 gm. A series of colored plates has been added to demonstrate the comparative servings of all types of foods recommended by the Food and Nutrition Board of the National Research Council. A long bibliography of thirty-eight pages is appended to the text, and there is a good index. The volume is well published and should be in all medical libraries and in the libraries of physicians interested in the subject.

**Animal Genetics and Medicine** By Hans Grüneberg, Ph.D., M.D., reader in genetics, University College, London. With a foreword by Sir Henry Dale, O.M., G.B.E., F.R.C. 12°, cloth, 296 pp. New York: Paul B. Hoeber, Incorporated, Medical Book Department of Harper & Brothers, 1947. \$5.50.

Dr. Grüneberg has confined his subject to the inherited diseases of laboratory rodents, omitting the domesticated animals, both large and small, because of the amount of space it would require for adequate coverage of the whole subject. Likewise, the subject of animal tumors has been omitted because it has been adequately covered in recent publications on cancer. The material is arranged according to the systems of the body, with special sections on the relation of animal to human congenital conditions. The beginning chapters discuss inherited diseases in general, the advantages and limitations in etiologic studies and the principles of developmental genetics. The two last chapters consider serology, including blood grouping, and disease resistance. A long bibliography concludes the text, and an attempt has been made to include wartime literature of Continental Europe. There are good author and subject indexes. The book is well published. The sheets were printed in Great Britain and bound in the United States. The author makes a plea for the proper utilization of material of interest to medicine now lying dormant in genetical periodicals seldom consulted by physicians. This unusual monograph should be in all medical reference collections.

## NOTICES

### ANNOUNCEMENTS

Dr. Robert B. Holden announces the opening of his office for the practice of internal medicine at 520 Commonwealth Avenue, Boston.

Dr. William D. Rowland announces the removal of his office from 180 Commonwealth Avenue to 140 Marlborough Street, Boston.

### NEW ENGLAND CONFERENCE OF INDUSTRIAL PHYSICIANS AND SURGEONS

The next meeting of the New England Conference of Industrial Physicians and Surgeons will be held at the Copley Plaza Hotel, Boston, on September 22.

### AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY, INC.

A number of changes in Board requirements and regulations were made at the annual meeting of the Board held in Washington, D. C., May 16 to May 22. New bulletins are now available for distribution upon application and give details of all new regulations. These relate both to candidates and to hospitals conducting residency services for training.

The next written examination and review of case histories (Part I) for all candidates will be held in various cities of the United States and Canada on Friday, February 4, 1949.

Application may be made until November 1, 1948. Application forms and bulletins will be sent on request to the American Board of Obstetrics and Gynecology, 1015 Highland Building, Pittsburgh 6, Pennsylvania.

### FEDERAL SECURITY AGENCY

Public Health Service  
Washington, D. C.

#### EXAMINATION FOR REGULAR CORPS

A competitive examination for appointment in the Regular Corps of the United States Public Health Service in the grade of assistant surgeon (first lieutenant) and senior assistant surgeon (captain) will be held in October. The written examination will be conducted October 4, 5, and 6 at places convenient to the candidates. The oral examination will be held at various points throughout the country.

All applicants must be at least twenty-one years of age and citizens of the United States, must present a diploma of graduation from a recognized medical school and satisfactorily pass a physical examination performed by Public Health Service officers.

Physicians beginning internship on July 1, 1948, will be admitted to the examination. Successful candidates will be placed on active duty in the Regular Corps upon completion of internship on July 1, 1949.

Applicants for the grade of assistant surgeon must have had at least seven years of educational and professional training or experience, exclusive of high school. Applicants for the grade of senior assistant surgeon must have had at least ten years of educational and professional training or experience, exclusive of high school.

Entrance pay for an assistant surgeon with dependents is \$5011 a year and for senior assistant surgeon with dependents \$5551 a year. This includes the additional pay of \$1200 for medical officers, as well as subsistence and rental allowance. Provisions are made for promotions at regular intervals up to and including the grade of senior surgeon (lieutenant colonel) and for selection for promotion to grade of medical director (colonel) at \$9751 a year. Retirement is authorized at either completion of thirty years' service or at the age of sixty-four. Full medical care including disability retirement at three-fourths pay is provided.

Application forms may be obtained from Public Health Service Hospitals, District Offices or by writing to the Surgeon General, United States Public Health Service, Washington 25, D. C.

## DIAGNOSTIC AND THERAPEUTIC PROBLEMS IN DIVERTICULITIS\*

C P LEROYER, JR, M D,† AND BENJAMIN V WHITE, M D‡

HARTFORD, CONNECTICUT

DIVERTICULOSIS and diverticulitis are relatively common in persons past the age of forty-five. Ochsner and Bagen<sup>1</sup> discovered that in all the patients registered at the Mayo Clinic in 1933, x-ray study showed diverticulosis in 0.4 per cent, and 7 per cent of all autopsies revealed the presence of diverticula. This corresponds with Morton's<sup>2</sup> figure of 6.5 per cent in 8500 autopsies at the University of Rochester. Among 24,620 cases in which barium enemas were performed Rankin and Brown<sup>3</sup> found diverticulosis in 5.6 per cent.

Diverticulitis occurs at some time in 17 to 27 per cent of all cases of diverticulosis. Rankin and Brown<sup>3</sup> reported the incidence to be about 17 per cent in 1300 cases of diverticulosis, and Abell<sup>4</sup> found it to be 10 to 20 per cent. Ochsner and Bagen<sup>1</sup> observed an incidence of 27 per cent, Smithwick<sup>5</sup> one of 25 per cent, and Willard and Bockus<sup>6</sup> one of 22 per cent.

Most of these analyses of diverticulosis and diverticulitis are concerned with the incidence, etiology and pathological features of the disease. For this reason these aspects are given only brief consideration in the review of the case material that forms the basis of this communication. Emphasis is placed, rather, upon the difficulties of diagnosis that arise from confusion with diseases affecting neighboring organs, and upon the complications.

During the twenty-year period, 1927-1946, 200 cases of diverticulitis were seen at the Hartford Hospital. Of these, 50 were complicated by perforation or obstruction. This incidence is much higher than that in the community at large, because many patients are selected for hospital admission because of symptoms attributable to the complications rather than to the disease itself.

Most of the cases of diverticulitis were seen in persons over forty-five with an antecedent history of spastic constipation or diarrhea. The inflammation in the diverticula was often accompanied by

chills and fever, crampy lower abdominal pain with localized soreness, and a recent change in bowel habits. On physical examination, there was almost invariably tenderness in the lower abdomen to the left of the midline, and a palpable, tender mass or muscle spasm was often found. The temperature was elevated in 60 per cent of the cases, and in 36 per cent there was a white-cell count of over 11,000. The erythrocyte sedimentation rate was frequently increased. Diverticula were evident on barium enema, and spasm was usually present. Sigmoidoscopic examination was seldom helpful. The treatment was medical unless complications arose.

### SIGNS AND SYMPTOMS

The diagnosis of diverticulitis was made by the clinical picture in addition to the x-ray findings in 161 cases, at operation in 32, by the clinical picture alone in 5, and at autopsy in 2. Of the 32 patients in whom the diagnosis was made at operation, 15 were suspected primarily to have acute appendicitis, and 17 were operated on with such preoperative diagnoses as pelvic inflammatory disease, acute cholecystitis, intestinal obstruction and ruptured ovarian cyst. In none of the 32 cases was a barium enema performed.

The leading symptoms and signs were similar to those described by other authors and need no comment (Table 1). However, there are two symptoms due to diverticulitis that bear more consideration—back pain and melena.

Pain in the lower back was noted in 20.5 per cent of the cases. Heretofore little emphasis has been placed on this symptom. By applying irritant solutions to the mucosa of the rectosigmoid through a sigmoidoscope, White and Jones<sup>7</sup> demonstrated that pain could be referred from the colon to the lumbosacral region. This radiation of pain is also encountered in mucous colitis and ulcerative colitis, both of which involve essentially the same portion of the sigmoid as diverticulitis. Thus, there is experimental evidence for back pain in lesions of the rectosigmoid. In diverticulitis this symptom is often part of the clinical picture.

\*From the Medical Service and the Gastroenterologic Clinic, Hartford Hospital.

†Assistant physician, Middlesex County Sanatorium, Waltham, Massachusetts; formerly assistant resident in medicine, Hartford Hospital.

‡Assistant professor of clinical medicine, Yale University School of Medicine; assistant visiting physician, Hartford Hospital.

Another symptom, often the presenting complaint, is the passage of blood by rectum. This may appear as free blood or as flecks on the fecal material. Melena occurred in 16.5 per cent of the cases, a figure that is consistent with those of other authors (Table 1). Ochsner and Bagen,<sup>1</sup> Smithwick<sup>5</sup> and Morton<sup>2</sup> showed that bleeding occurs in diverticulitis more often than is generally believed. Rankin and Brown<sup>3</sup> found that melena was present

times when great confusion exists. Smithwick<sup>5</sup> found that an incorrect diagnosis was made in 26 of 64 cases of acute diverticulitis, a 40.5 per cent of error on initial diagnosis. The three conditions most often confused with diverticulitis are appendicitis, carcinoma of the sigmoid colon and masses involving the structures of the genitourinary tract.

Acute appendicitis is often difficult to differentiate from diverticulitis, and in our series 15 patients

TABLE 1 *Leading Symptoms and Signs in Cases of Diverticulitis*

AUTHOR	NO. OF CASES	AVERAGE AGE	SEX RATIO	CONSTIPATION	DIARRHEA	BACK PAIN	MELANA	FEVER	CRAMPY ABDOMINAL PAIN	WHITE CELL COUNT PER 11,000
Ochsner and Bagen <sup>1</sup>	151	yr 45.0	275:100	58%	26%	5%	22.0%	26%	—	—
Morton <sup>2</sup>	111	44.5	10:10	45	37	—	32.0	29	94	79
Smithwick <sup>5</sup>	333	50-60	10:10	—	—	—	15.7	—	—	—
Willard and Bockus <sup>4</sup>	72	55	10:10	44	15	—	7.0	—	—	—
LeRoy and White	200	60	10:10	50	31	20.5	16.5	59	80	36

in 39 of 142 cases, an incidence of 27 per cent. In discussing Smithwick's<sup>5</sup> paper, C. C. Lund cited a case at the Boston City Hospital in which the chief complaint was severe melena. Soon after admission 1500 cc. of blood was expelled in a bedpan. The patient was operated on as an emergency, and a ruptured diverticulum was found to have involved a large blood vessel, causing extensive intraluminal hemorrhage. In our series, melena was the chief complaint in 6 cases, and in 1 of these the bleeding was extensive enough to require a transfusion.

#### ROENTGENOLOGIC FINDINGS

Spriggs and Marxer<sup>8</sup> pointed out the roentgenologic findings of a prediverticular state that could be recognized before full-blown diverticula had formed. They also described irritability, spasm and narrowing of the lumen as indications of diverticulitis.

Of the 200 Hartford Hospital cases, 161 had barium enemas that showed diverticulosis in the colon, and 133 of these demonstrated definite spasm of the sigmoid, with narrowing of the lumen. The 28 cases of diverticulosis with no spasm had a clinical picture that, with the finding of diverticula by x-ray study, was consistent with the diagnosis of diverticulitis. The X-Ray Department demonstrated a mass by barium enema in 33 of the 161 cases, and the mass was invariably in the sigmoid region. However, the appearance of a mass on x-ray examination is not necessarily diagnostic, since it may be seen with multiple noninflamed diverticula, or it may indicate an unrelated carcinoma or other pathologic process.

#### DIFFERENTIAL DIAGNOSIS

Whereas diverticulitis is often a clear-cut disease that presents no diagnostic difficulties, there are

were operated on with this preoperative diagnosis. In all the appendix was found to be normal, and on exploration an acute, inflammatory diverticulitis of the sigmoid was discovered. In 2 cases the sigmoid loop was to the right of the midline, so that with the findings of crampy abdominal pain, tenderness in the right and middle portions of the abdomen, slight fever and leukocytosis, the diagnosis of acute appendicitis was made. Both patients were found to have normal appendixes.

The following case illustrates the difficulty in differential diagnosis between appendicitis and diverticulitis.

**CASE 1.** A 68-year-old man had been well until 10 hours before admission, when he suddenly developed a rather sharp constant pain in the lower back. After several hours the pain worked around to the right lower quadrant. The last bowel movement had occurred several hours before onset of the pain, and the patient vomited three times. His bowel habits had been normal, and there were no urinary symptoms.

The past history was noncontributory.

Physical examination revealed a well developed, well nourished man in moderate abdominal pain. The pertinent findings were confined to the abdomen, where there was persistent spasm, with rebound tenderness in the right lower quadrant and in the midline. Rectal examination revealed slight soreness on the right.

The temperature was 99.6°F. Urinalysis was negative. The white-cell count was 13,000, with 88 per cent neutrophils and 12 per cent lymphocytes.

At operation a normal appendix was found, and further exploration was carried out. In the midsigmoid there was an area of spasm and induration, and several diverticula were seen. Appendectomy was then performed. On the 9th post-operative day a barium enema showed a localized spastic area in the sigmoid, with numerous diverticula.

The only symptom unusual for appendicitis in this case was the initial pain in the lower back, a finding that was present in 20.5 per cent of the 200 cases of diverticulitis.

Carcinoma of the sigmoid is frequently confused with diverticulitis. The clinical diagnosis is often impossible even with the help of barium enemas,

nd at operation under observation and palpation is sometimes very difficult to differentiate the two lesions. The final diagnosis in this type of case usually rests with the pathologist. The association of carcinoma and diverticulitis has evoked considerable discussion in the literature. Rankin and Brown<sup>2</sup> found carcinoma to be present in 4 of 227 cases of diverticulitis. Smithwick<sup>5</sup> encountered the same lesion in 2.9 per cent of 309 cases of diverticulitis. It is now generally believed that the two conditions may exist coincidentally and that carcinoma of the sigmoid rarely, if ever, develops from pre-existing diverticulosis.

Narrowing of the rectosigmoid or evidence of a mass was demonstrated by barium enema in 33 of the 200 cases of diverticulitis under consideration. In none of the 33 could a differential diagnosis be made on the radiographic findings alone. Schatzki<sup>9</sup> states that the differential diagnosis of carcinoma of the sigmoid and diverticulitis by x-ray study is easy in most, difficult in some and impossible in a few cases.

The following case demonstrates the difficulty in differentiating carcinoma of the sigmoid from diverticulitis.

**CASE 2** A 67-year-old housewife was admitted to the hospital for cramp-like, lower abdominal and rectal pain of 2 weeks' duration, which was worse during defecation. She also noted bright-red blood with mucus in the stools, and she had moderate tenesmus with a desire to defecate three or four times a day. Her appetite was poor, and she had lost 16 pounds of weight in 2 years. She had had no nausea, vomiting or urinary complaints.

Physical examination showed a well developed but poorly nourished woman who appeared anemic. Tenderness without spasm was noted in the middle-lower portion of the abdomen and in the right lower quadrant. No masses were palpable. Rectal examination was negative. Sigmoidoscopy revealed one small area of discolored bowel just above the third valve, and there was a mass that prevented further observation. No blood was seen.

Examination of the blood disclosed a red-cell count of 3,700,000 with a hemoglobin of 12 gm. and a white-cell count of 10,000. Two stools showed strongly positive benzidine tests. A barium enema was not performed.

On the 11th hospital day the patient was explored with the preoperative diagnosis of carcinoma of the rectosigmoid. The mass that was found in the rectosigmoid was to the right of the midline and seemed to involve the lumen of the bowel. The surgeon believed it was carcinoma. A colostomy was made. Four weeks later, when resection was performed, the mass, which had been obstructing the bowel, was found to be smaller, and several diverticula were encountered. After excision an end-to-end anastomosis was performed. The colostomy was not closed at that time. The specimen consisted of a portion of colon 50 cm. in length. There were a few small diverticula lined by normal colonic mucosa, but no evidence of neoplasia was found.

The patient was readmitted 5 months later, and a barium enema revealed no obstruction between the rectum and the colostomy, but showed multiple diverticula and considerable spasm of the sigmoid. At that time the colostomy was closed, and the patient made an uneventful recovery.

This case is significant because of the difficulty in differential diagnosis. Carcinoma was originally considered because the chief complaint was melena. This symptom is more common in acute diverticulitis than has generally been realized. The

appearance of the lesion at operation was also misleading. The similarity of such an inflammatory mass to carcinoma on inspection and palpation is so great that not infrequently the final diagnosis rests with the pathologist.

Diverticulitis may be confused with diseases of the lower genitourinary system. The primary complaints may be dysuria, frequency and burning on urination, and the patient may first be studied from a genitourinary point of view. Pressure on the uri-

**FIGURE 1** Cystogram Showing a Soft-Tissue Mass Producing Pressure on the Posterior Wall of the Bladder and Rotating It Slightly to the Right.

The barium-filled diverticula in that region indicate that the mass probably represented an inflammatory diverticulitis.

nary bladder by an inflammatory mass, secondary to an acute or recurrent diverticulitis, accounts for the bladder symptoms (Fig 1). Such a mass may be found by rectal examination. Extrinsic pressure defects of the urinary bladder may be observed cystoscopically and may be attributed to neoplasm of the rectum or internal genitalia. The following case illustrates the diagnostic confusion that exists when signs and symptoms referable to the bowel and urinary bladder are present.

**CASE 3** A 51-year-old office worker had been entirely well until 1 year before admission, when he began to have pain on defecation. At the time of admission it was relatively severe and he had three to five bowel movements daily, with increasing pain at each successive stool. There had been no diarrhea. Bright-red blood had been present in the stools on several

occasions. In addition, the stools had often been covered by mucus. Recently there had been intermittent, dull, aching lower abdominal pain and urinary frequency.

Physical examination revealed a well developed, slightly thin man in no distress. On rectal examination, there was a firm, rounded mass occupying a position practically in the midline and yet extending well out on each side in the region of the seminal vesicles. It did not suggest a tumor of one or the other seminal vesicles. Distally, it extended down to and was apparently confluent with the prostate.

The temperature, pulse and respirations were normal.

Several urinary specimens were normal, and a culture was negative. The hematocrit was 47 per cent, and the serum protein 6.2 gm per 100 cc.

On proctoscopy a mass was seen above the prostate. The mucosa of the rectum was intact but puckered down at the junction of the mass with the prostate.

Several needle-punch biopsies were taken. Microscopical examination showed hyalinized strands of fibrous tissue in

sigmoid with an end-to-end anastomosis was carried out. Microscopical study of the sections revealed many diverticula, two of which showed infected sinus tracts into the sigmoid mass. Another section demonstrated that the seminal vesicles were surrounded by chronic inflammatory tissue.

The final diagnosis was diverticulitis of the sigmoid, with secondary seminal vesiculitis.

This case demonstrates how an acute, inflammatory diverticulitis can drain to the rectovesical pouch, with formation of a secondary inflammatory mass closely associated with the internal genitalia and bladder wall.

In the series reviewed, 18 patients with diverticulitis had urinary symptoms, and of these, 3 developed bladder fistulas.

### COMPLICATIONS

The complications of diverticulitis are of interest in terms of incidence and of surgical management. Smithwick<sup>5</sup> found that 19.2 per cent of 333 cases of

TABLE 2 Complications in Cases of Diverticulitis

diverticulitis required surgery and that the incidence of such surgical complications in persons over the age of forty was 1/2500.

Perforation may lead to localized abscess formation, peritonitis with ileus, mechanical obstruction or fistula formation. These are the most common complications. However, mechanical obstruction

TABLE 3 Location of Abscess in 32 Cases

which there was a chronic inflammatory reaction. No evidence of a neoplastic process was made out.

On the 4th hospital day, cystoscopy was performed. The trigone was elongated, and the ureteral orifices were farther apart than normal. At a level 1.0 cm above the orifices, a band of trabeculation was seen, which persisted on distention. The bladder mucosa was normal. X-ray films of the pelvis, after the bladder had been injected with an opaque medium, showed the ureters and the floor of the bladder to be pushed forward. The upper urinary tract was normal.

The patient was explored extraperitoneally through a suprapubic incision. A lemon-sized, inflammatory mass was found in the rectosigmoid attached to the posterior aspect of the bladder. This mass seemed to bulge into the bowel. On palpation, deep in the pelvis, a second mass of equal size was found. This occupied the region of the seminal vesicles and extended distally under the trigone of the bladder to the prostate. Frozen sections proved that this mass surrounded the seminal vesicles and was not primary in them. The primary lesion was in the bowel, and the indurated inflammatory mass was secondary (Fig. 2). A wide resection of the lesion in the

due to narrowing of the bowel lumen by a local inflammatory mass may be found in a smaller portion of patients. Twenty-five per cent of the 200 Hartford Hospital cases developed a complication. Local abscesses secondary to perforation were by far the most common (Table 2). Smithwick<sup>5</sup> reported local

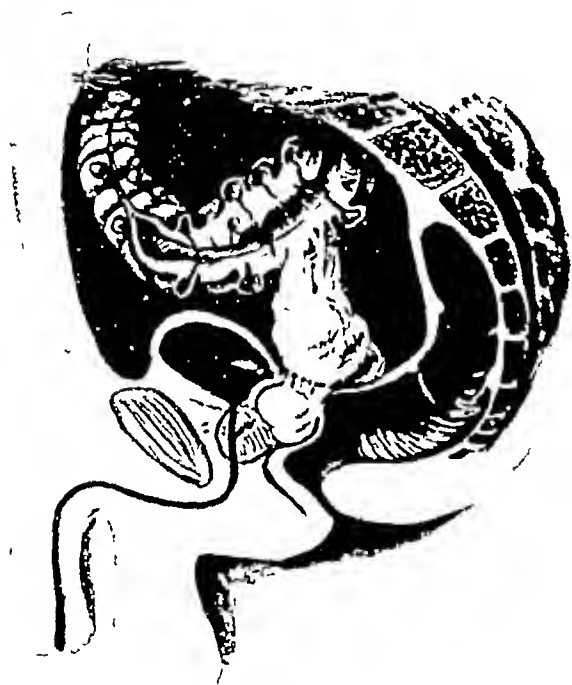

FIGURE 2 Diagrammatic Sketch of the Findings at Operation in Case 3, Showing a Diverticulitis of the Sigmoid, with a Large Inflammatory Mass.

A second mass can be seen above the prostate compressing the trigone of the bladder and bulging into the rectum.

abscesses in 11.9 per cent of 506 cases, with a mortality of 9.3 per cent.

Table 3 indicates the location of the abscesses in the Hartford Hospital series. Of 18 abdominal abscesses, 13 were drained with no further complications. Four led to intestinal obstruction, and 1 resulted in death from generalized peritonitis. However, of 14 pelvic abscesses, 6 developed into fistulas. Three of these drained into the bladder, and 3 into the vagina. The over-all incidence of fistulas was 3 per cent. Morton<sup>2</sup> found 22 cases of fistula formation in 83 complicated cases of diverticulitis. Smithwick<sup>5</sup> records an incidence of 13.1 per cent of spontaneous bladder fistulas in 611 complicated cases. Higgins<sup>10</sup> noted that of 160 cases of vesico-colonic fistula, 57.5 per cent were secondary to diverticulitis.

Mechanical obstruction in the rectosigmoid by an inflammatory mass due to diverticulitis occurred

other neoplastic lesions, and complicates the differential diagnosis.

The 25 per cent incidence of perforations and inflammatory obstructions is undoubtedly much higher than that in the community at large, because such complications serve as indications for admission to a hospital. Among 18 patients with abscesses within the peritoneal cavity, there was 1 with generalized peritonitis, and 4 others had intestinal obstruction secondary to localized inflammation. On the other hand, among 14 patients with abscesses in the pelvis, fistulas were encountered in 6. Hence, it appears that inflammatory masses within the peritoneum often lead to intestinal obstruction, whereas those in the pelvis frequently result in fistulas.

### SUMMARY

The clinical features of 200 cases of diverticulitis treated at the Hartford Hospital between 1927 and 1946 are reviewed.

The relative incidence of the leading symptoms and signs was essentially similar to those generally reported. A notable exception was the occurrence of pain in the lower back as a prominent feature in 20.5 per cent of the cases. A finding in accord with other authors' experiences, but worthy of special emphasis, was the presence of melena in 16.5 per cent.

Diagnostic confusion occurred most frequently in cases that presented signs suggestive of acute appendicitis, and in those in which masses in the lower abdomen or pelvis could not be differentiated clinically from carcinoma of the bowel or from genitourinary lesions such as ruptured ovarian cyst and carcinoma of the seminal vesicles or prostate.

Complications were encountered in 50 cases, or 25 per cent. These included 7 of obstruction secondary to ligneous induration of the affected sigmoid and 43 perforations. Thirty-two of the latter led to local abscesses, 6 to fistulas, 4 to mechanical obstruction, and only 1 to generalized peritonitis.

in 7 cases, an incidence of 3.5 per cent. All patients recovered after operation.

Table 4 indicates that among the 200 Hartford Hospital cases 63 operations were carried out, 19 of them for diagnostic purposes. In all there was acute diverticulitis of the sigmoid. Six patients were operated on for other conditions (Table 4), and acute diverticulitis was found incidentally. Thirty-eight surgical procedures were carried out.

### DISCUSSION

Most of the findings of this review of 200 cases of diverticulitis are in accord with those of other authors. From the diagnostic point of view two features are striking: the relatively high incidence of back pain and the frequency of bleeding from the rectum. The latter is somewhat disconcerting because it detracts from the significance of blood in the rectosigmoid as an indication of polyps or

## RELAPSING KALA-AZAR\*

## Report of a Case with Cure Effected by Stilbamidine

PAUL R. WILNER, M.D.,† AND MAJOR THOMAS A. HAEDICKE, M.C., A.U.S.‡

WASHINGTON, D. C.

THERE have been many reports concerning the increased incidence of certain tropical diseases in the United States during the postwar period. Service personnel were exposed to and contracted more tropical diseases than any previous group of citizens. There were many cases of dysentery, malaria and dengue among the armed forces. However, the incidence of more exotic tropical diseases, such as leishmaniasis, relapsing fever, cholera and trypanosomiasis, was fortunately much less.

During the immediate postwar period, it became apparent that no widespread outbreaks of tropical diseases in this country would occur chiefly because of the climate, housing and sanitation and the absence of certain vectors. Relapsing and delayed primary attacks of malaria have not been uncommon, and there is no doubt that amebiasis is more evident. Other tropical diseases may be seen sporadically, not only because of a residual focus in returned veterans but also because of increased air travel.

Kala-azar may be encountered. On the basis of a preliminary account of Army medical records, approximately 56 cases of visceral leishmaniasis were reported among Army troops during the period 1942-1945. The diagnosis should be considered in every obscure illness since the over-all untreated mortality throughout the world is 95 and the treated mortality less than 5 per cent. A recent review of the disease in the United States by Ecker and Lubitz<sup>1</sup> emphasizes that kala-azar demands a higher index of suspicion among physicians in the United States.

The clinical picture and course of kala-azar are usually typical. The disease is characterized by an irregular fever, chronicity, splenomegaly, emaciation, anemia and leukopenia. However, the disease may be quite mild and vague. Armstrong<sup>2</sup> has shown that patients may be ill with kala-azar and still have very few obvious complaints. The clinical course varies with the geographic origin of the disease. We have found the disease acquired in the Sudan to be most severe.

The diagnosis of kala-azar is sometimes very difficult. The history and physical examination may be typical, but the demonstration of the causative

organism, *Leishmania donovani*, is necessary for diagnosis. Packchianian<sup>3</sup> believes that the diagnosis may be made only by culture of *L. donovani* from the blood, bone marrow, spleen or liver. Scovell<sup>4</sup> does not consider a positive culture necessary. We have not found the peripheral blood cultures of much value in establishing the diagnosis in Americans. The material aspirated from the spleen and bone marrow produces 95 per cent of positive smears and cultures.

Other tests, such as those using aldehyde, antimony and distilled water, may be useful. Feldman<sup>5</sup> has found the formol-gel test of help in suggesting the diagnosis. As this test is based upon the hyperglobulinemia present in kala-azar, it is positive in any condition producing hyperglobulinemia. It was negative in the case reported below.

Antimony preparations, especially neostibosan and urea-stibamine, are the present drugs of choice for therapy. The response to treatment, like the severity, depends on the geographic origin of the disease. Burchenal and Woods<sup>6</sup> reported 3 cases acquired in the Mediterranean area, 2 of which responded poorly to the antimonials. The patients of Waud and Kruger<sup>6</sup> responded to a relatively small amount of antimony. However, their follow-up study was probably of too short duration to meet the criteria for cure of visceral leishmaniasis brought out in a recent review by Marple.<sup>7</sup> It should be emphasized that these patients cannot be considered cured unless they are followed for a minimum of six months.

Hargreaves<sup>8</sup> reported several cases from Italy and Sicily that did not respond to antimony and were treated with urea-stibamine and stilbamidine. His results were satisfactory in the treatment of all cases of Indian and Mediterranean kala-azar. May and Baker,<sup>9</sup> of London, recommend pentamidine for the treatment of patients who relapse after antimonial therapy. It is possible that some kala-azar patients develop resistance to all forms of chemotherapy. In a case recently published, which was complicated by severe anemia and finally cured by splenectomy, the patient received large amounts of antimonials and stilbamidine over a period of two years with only temporary improvement.<sup>10</sup>

Stilbamidine was first brought into clinical prominence by the work of Napier and Sen Gupta<sup>11</sup> at the London School of Tropical Medicine in an effort to find a drug that would cure antimony-resistant kala-azar. It became apparent that all patients not

responding to antimony therapy were cured with stilbamidine

The administration of stilbamidine presents several problems, and a detailed discussion is therefore presented. The di-isethionate form of the drug is more soluble and easier to prepare. A maximum of 15 mg per pound of body weight is given in any one day. The entire dose should be mixed with approximately 250 cc of physiologic saline solution or distilled water to prevent thrombosis of veins. An initial dose of 40 mg is given to each patient, and this is followed every day with a higher dose until the maximum dose has been attained. A fresh preparation of the solution should be made daily, and it should be given intravenously. Oastler and Fidler<sup>12</sup> demonstrated that stilbamidine is much more hepatotoxic and nephrotoxic in dogs when exposed to light prior to administration. A fresh preparation prevents the occurrence of liver damage sometimes noted in patients. A total dose of approximately 4 gm is considered adequate. Napier and Sen Gupta<sup>11</sup> administered as little as 15 gm to patients with kala-azar who had previously relapsed after treatment with antimony.

Patients seem to tolerate stilbamidine well, but a few toxic vasomotor manifestations should be mentioned. Various subjective symptoms, usually of a transient nature, include flushing of the face, giddiness, breathlessness, faintness, nausea, vomiting, epigastric discomfort, salivation, sweating, tachycardia and occasionally collapse. After the

tom complex generally begins three or four months after administration has been completed and may last for several years.

The following case is presented because of several interesting features in diagnosis and treatment. The patient had malaria and amebiasis in addition to kala-azar and presented an apparent cure when treated with quinine, quinacrine (atabrine) and emetine. One sternal-marrow puncture was negative, and the *L. donovani* bodies were found on only two of the nine slides made from the second puncture. Two courses of neostibosan failed to cure the infection. One course of stilbamidine was successful.

### CASE REPORT

A 36-year-old former Army officer was overseas in India, upper Assam and China from March, 1944, to November, 1945. In August, 1944, he had an acute attack of tertian malaria treated with quinine and atabrine. Intermittent diarrhea was present and was occasionally treated with small amounts of sulfaguanidine and diodoquin.

The patient felt well on his return to the United States until the onset of his present illness on March 3, 1946. This was characterized by chilliness, fever, sweats and malaise. He was first seen on March 6, when the temperature was 102°F, the spleen was palpable three fingerbreadths below the costal margin and the liver was tender, its edge being palpable two fingerbreadths below the costal margin. A blood smear revealed *Plasmodium vivax*. Atabrine therapy was followed by an apparent response. Quinine sulfate (0.6 gm daily) was prescribed as a maintenance dose.

On March 25 the patient reported a recurrence of malaise, chilliness, fever and sweats and was confined to bed at home. His temperature fluctuated widely, readings of 104° and 105°F being reported and the minimum being 99°F. Drenching sweats were prominent, and insomnia was troublesome. There was no frank chill. An increased looseness and frequency of

first few injections of the drug there is usually a fall in blood pressure, which is frequently marked. As the blood pressure returns to its normal level, most of the symptoms disappear, usually within half an hour or so. These reactions may be controlled or prevented by an injection of epinephrine.

Nervous symptoms, including paresthesia, peripheral neuritis, paraplegia and trigeminal neuropathy, may develop after treatment has been continued for some time, suggesting a cumulative action. The most important of these is an unexplained bilateral trigeminal neuropathy in which light touch is absent and pain and temperature sensation is preserved along the course of the fifth cranial nerve. Numbness and tingling over this entire area may be a real complaint. This symp-

stools was noted, which continued for several weeks. At times, the patient was incontinent. A pasty type of pallor was present.

The spleen was hard and palpable three or four fingerbreadths below the costal margin. The liver edge was palpable two fingerbreadths below the costal margin and was tender and sharp. On March 28 examination of the blood disclosed a red-cell count of 4,090,000, with a hemoglobin of 11.5 gm (76 per cent), and a white-cell count of 3700, with 49 per cent neutrophils, 10 per cent band forms, 39 per cent lymphocytes and 12 per cent monocytes. Malaria smears were negative. Urinalysis was negative. Quinine sulfate (0.6 gm three times a day) was administered from March 25 to 29, with no response objectively or subjectively.

On March 29 the patient was admitted to a hospital. His course was stormy. Chills, fever, vomiting, diarrhea, drenching sweats, apprehension and disorientation were prominent. His temperature had a tendency to double daily spikes. Six to eight liquid stools occurred daily. Vomiting occurred two or three times daily. The physical findings remained the same. The patient began to look emaciated. The results of laboratory studies performed from March 30 to April 2 are presented

in Table 1 Urinalysis was negative. A sternal puncture on April 3 was negative for *L. donovani*. Specific treatment with atabrine (12 gm) and penicillin (640,000 units), in addition to supportive measures, was ineffective.

He was transferred to Walter Reed General Hospital on April 4. The white-cell count was 2100, with 60 per cent

ulins of 1.74 gm. The formol-gel test was negative. An x-ray film of the chest was normal.

The patient failed to respond to emetine, and his temperature rose to 104°F. It was believed that he had either an abscess of the liver that was not responding to emetine or kala-azar, which had not been proved. Fluoroscopic study

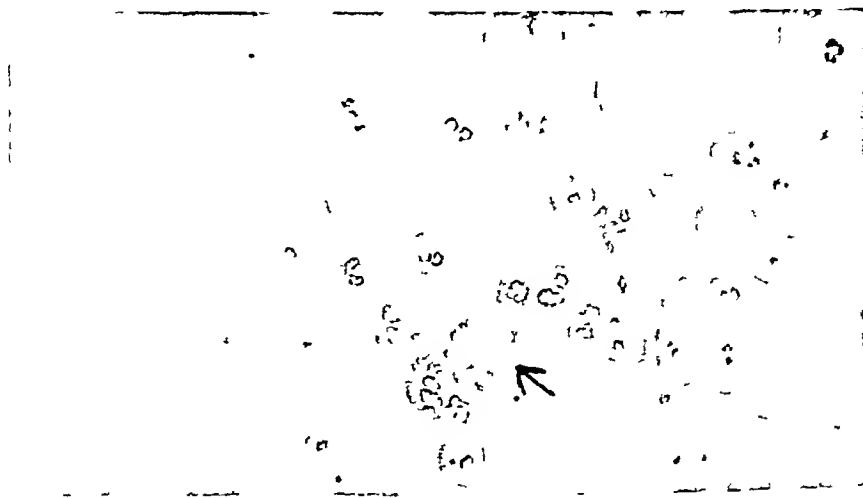

FIGURE 1 Endothelial Cell Containing Leishman-Donovan Bodies (Arrow)

neutrophils, 38 per cent lymphocytes and 2 per cent monocytes. The total protein was 5.75 gm per 100 cc, with an albumin of 3.8 and a globulin of 1.95 gm per 100 cc. A blood

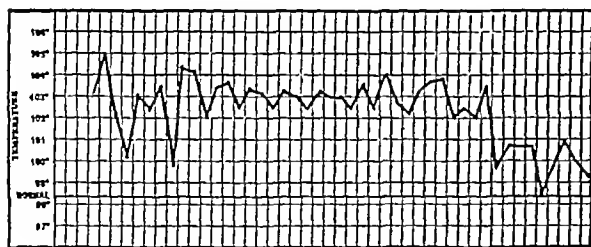

FIGURE 2 Temperature from March 29 to April 5

culture, complement-fixation test for amebiasis, Widal test on the stools and stool culture were negative, as was the formol-gel test.

The differential diagnoses were amebic hepatitis, visceral leishmaniasis and typhoid fever. Because cysts of *E. histolytica* were found in the stools and the liver was enlarged and tender, a course of emetine (0.55 gm) was administered. A dramatic response to emetine was noted. The temperature dropped to normal levels, and the appetite improved, the red-cell count rose to 4,000,000, and the white-cell count to 5000. The patient felt well. He was discharged on April 14 and he continued to improve. The size and tenderness of the liver decreased, but the spleen remained the same size.

This apparent cure continued for approximately 2 weeks, when he began running a low-grade fever, which gradually increased. Malaise recurred, and he was readmitted to Walter Reed General Hospital on May 1 for further treatment of what was thought to be an amebic abscess. The entire picture was identical with that during the previous episode with splenomegaly, hepatomegaly and the following laboratory studies: negative malarial smears, a red-cell count of 2,440,000, with a hemoglobin of 43 per cent, and a white-cell count of 2750, with 59 per cent neutrophils, 38 per cent lymphocytes, and 2 per cent monocytes. The total protein was 5.65 gm per 100 cc, with an albumin of 3.91 and a glob-

ulin of 1.74 gm. The formol-gel test was negative. An x-ray film of the chest was normal.

The patient failed to respond to emetine, and his temperature rose to 104°F. It was believed that he had either an abscess of the liver that was not responding to emetine or kala-azar, which had not been proved. Fluoroscopic study

of the right leaf of the diaphragm demonstrated good mobility on inspiration and expiration. The white-cell count remained low. In view of these findings, abscess of the liver or diffuse amebic hepatitis was deemed unlikely. A repeated sternal puncture revealed *L. donovani* organisms on two of the smears, and a culture of the aspirated blood from the sternal marrow was later reported positive for *L. donovani* (Fig 1). This confirmed the diagnosis of kala-azar. A good response was brought about with a total of 2.7 gm of neostibosan, and he was discharged on May 20, afebrile and well. The red-cell count was 3,830,000, with a hemoglobin of 60 per cent, and the white-cell count was 5250.

The patient was followed during the months of June and July periodically. Toward the beginning of July, it was apparent that he was not cured of his disease. Although he ate well and led a restful life, he did not fully regain his strength. His color was pasty. His liver and spleen continued to be palpable. The hemoglobin and red-cell count dropped from 85 per cent and 4,390,000 on June 27 to 70 per cent and 3,580,000 on July 10. It was believed that another course of neostibosan should be instituted. This was carried out from July 15 through 26. He received a total of 3.45 gm. of neostibosan at home with apparent complete remission. There

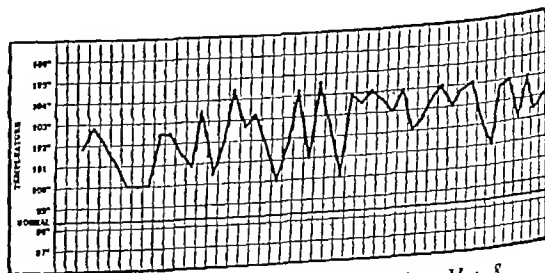

FIGURE 3 Temperature from May 1 to May 8

was a reduction in the size of the liver and spleen, although they still remained palpable.

After 1 month of apparent cure, a recurrence of fever and malaise began on August 24. This continued, and he was

mitted for the third time to Walter Reed General Hospital on August 30, remaining until September 20.

On admission it was evident that the patient was markedly icteric. The temperature was 101°F, the spleen was palpated three fingerbreadths below the left costal margin on deep inspiration (one and a half fingerbreadths at rest) but as not tender. The liver was not palpable.

On August 31 examination of the blood revealed a red-cell count of 2,100,000, with a hemoglobin of 46 per cent, and a white-cell count of 3100, with 36 per cent lymphocytes, 6 per cent monocytes, 3 per cent basophils and 55 per cent neutrophils.

On September 20 the red-cell count was 3,750,000, with hemoglobin of 78 per cent, and the white-cell count 6300, with 45 per cent neutrophils, 49 per cent lymphocytes, 4 per cent monocytes, 2 per cent eosinophils and 0.8 per cent reticulocytes. Urinalysis was negative. The total protein was 8 gm per 100 cc, with an albumin-globulin ratio of 1:4:1.

Stilbamidine therapy was instituted, consisting of 150 mg per day intravenously for the first 2 weeks and 300 mg daily or the last week, a total of 4,325 gm being given in the 21-day period. The temperature reached normal levels on the 12th day of therapy and has continued so to date. The edge of the spleen was palpated five fingerbreadths below the left costal margin during the first 2 weeks of therapy and gradually receded. On the 21st day of therapy, the spleen extended only one and a half fingerbreadths below the costal margin on inspiration, and the edge was barely palpable at rest.

The temperature curves during the hospital admissions are demonstrated in Fig. 2-5.

After his discharge from Walter Reed General Hospital on September 20, the patient continued to feel well. He regained his strength and carried on his normal activities.

On October 16 the liver edge was not felt and the tip of

## SUMMARY

A case of kala-azar is reported. Difficulties in diagnosis were encountered, emphasizing the varied nature of the disease. The patient relapsed after two courses of neostibosan. Complete cure was obtained with 4,325 gm of stilbamidine. It is

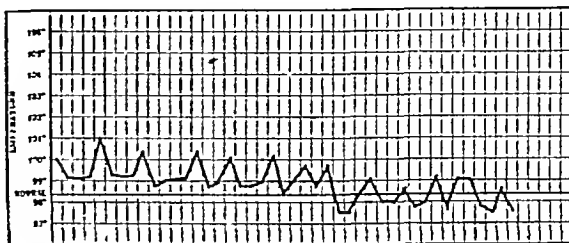

FIGURE 5 Temperature from August 31 to September 5

suggested that kala-azar be included in the differential diagnosis of any obscure febrile illness. Stilbamidine may be considered efficacious in relapsing visceral leishmaniasis until less toxic drugs have been proved to be of value.

his spleen was just barely palpable. On January 15 1947, he noticed a numbness of his upper lip, both cheeks, ears and temples. There was definite anesthesia to light touch, but no change in pain or temperature sensation. Motor components were unchanged. This was thought to be dissociated anesthesia of the fifth cranial nerve.

On February 24 the hemoglobin was 91 per cent, the red-cell count 4,470,000, and the white-cell count 6200 and the patient reported improvement in the neurologic sensations.

On June 15 there was continued improvement in the neurologic symptoms. There had been no recurrence of fever or malaise, although the tip of the spleen was still palpable.

## CESAREAN SECTION AT THE BOSTON CITY HOSPITAL, 1936-1946\*

DANIEL J MCSWEENEY, MD,† AND ARTHUR J HASSETT, MD‡

## BOSTON

AT THE Boston City Hospital in the ten-year period from 1936 to 1946 there were 961 cesarean sections—3.3 per cent of 28,341 deliveries, or 1 cesarean section in every 29 cases. This incidence is about the same as that reported by Duncan and Doyle<sup>1</sup> for the previous ten years, in which there were 703 sections in 22,880 deliveries, an incidence of 3.07 per cent. The Boston Lying-in Hospital<sup>2</sup> reported an incidence of 3.4 per cent on its ward service, and the State of Massachusetts 3.3 per cent.<sup>3</sup> These figures suggest a general attitude of conservatism throughout Massachusetts in the performance of cesarean section, especially in the larger public ward service in the city of Boston.

From 1936 to 1939 there was a steady increase in the percentage of cesarean sections (Table 1),

TABLE 1 Yearly Incidence of Cesarean Section

YEAR	NO OF DELIVERIES	NO OF CESAREAN SECTIONS	INCIDENCE %
1936	3180	84	3.5
1937	3295	135	4.0
1938	3320	142	4.2
1939	3262	88	2.7
1940	3225	83	2.5
1941	2969	91	3.0
1942	2918	81	2.7
1943	2447	96	3.9
1944	1964	82	4.1
1945	1761	79	4.5

which gave way to an abrupt decline in 1939, when x-ray pelvimetry was adopted as an additional check on a patient's ability to deliver through the natural channels. Since 1943 surgeons have been more radical in the choice of abdominal delivery under the protecting influence of the blood bank, the sulfonamides and penicillin. The present tendency seems everywhere to be a broadening of the indications for the cesarean operation.

## AGE

Patients thirty-five years of age and over, called injudiciously "the elderly group," comprised 70 per cent of the series. These patients suffer more of the complications requiring cesarean section, and protection of the baby of the elderly primigravida provokes more serious consideration than

that of the younger gravida with a longer span of reproductive years ahead of her. In addition, prolonged labor and difficult forceps deliveries seem to cause in the former group more chronic debilitating conditions, such as prolapse, cystocele and relaxations of the pelvic floor.

## PARITY

Twenty-eight per cent of the sections were done on primigravidas. In the remaining 72 per cent constituting the multiparous cases, 606, or 87 per cent of 689 cases, were repeat sections. Only 83 cases (8 per cent of the total series) of primary cesarean section were done on multiparas.

The extraordinary number of repetitions of abdominal hysterotomy (Table 2) is due to the fact that no sterilizations are done at the Boston City Hospital, nor is a Porro cesarean hysterectomy done unless there is definite uterine disease to warrant its adoption. It is interesting that there were only 6 ruptured uteri in the decade of this study, 2 traumatic and 4 occurring in patients with scars from previous cesarean sections, all of whom had had only one previous section. There were no ruptured uterine scars in the 602 other

repeat sections, in 257 of which the patients were experiencing abdominal delivery for the third time or more frequently.

## INDICATIONS

The indications for cesarean section are presented in Table 3. If a patient has had a section on her first delivery she is invariably treated in like manner in subsequent pregnancies. On the other hand, if she has had a vaginal delivery without difficulty prior to her first section and there was no sepsis after the cesarean section, she is given a test of labor under careful observation. If the cervix yields readily and there is no evidence of dystocia, delivery is effected through the natural route as soon as full dilatation is attained. If a patient has

\*From the Department of Obstetrics, Boston City Hospital and Boston University School of Medicine.

†Professor of clinical obstetrics, Boston University School of Medicine; assistant visiting obstetrician, Boston City Hospital.

‡Formerly resident in obstetrics and gynecology, Boston City Hospital and assistant in obstetrics, Boston University School of Medicine.

and more than one cesarean section she is not allowed to go into labor, but a repeat section is done within the last four weeks of pregnancy as soon as the estimated size of the fetus offers fair assurance that the baby will weigh approximately 5 pounds or over.

The abdominal deliveries for disproportion since 1939 were done only after x-ray pelvimetry demonstrated inadequacies in the size and shape of the pelvis and then only after a fair test of labor. In his clinic the incidence of disproportion requiring cesarean section is about 1 in 100 cases.<sup>4</sup>

Uterine inertia, which seems to be interrelated with cervical dystocia, accounted for 36 of the operations. In these most disconcerting cases there is no discrepancy between the fetal head size and that of the pelvis and yet the uterine contractions and the rigidity of the cervix fail to allow natural termination of labor. Contraction-ring dystocia may rightfully be included in cervical dystocia, making a total of 40 cases, or 4 per cent of the cesarean sections being done for abnormalities in the propulsive factors of labor. This, we believe, is a comparatively low incidence.

Primiparous breech delivery was the causative factor in only 1.5 per cent of the cases. Of 1200 breech presentations only 17 cases, all in primiparas, required cesarean section. X-ray pelvimetry is done routinely in all cases of primiparous breech delivery, and an adequate test of labor allowed before the decision is made to perform an abdominal delivery.

Previous gynecologic plastic operations accounted for but 2 cases of the series. The rarity of this indication is due to the conservative policy of performing extensive vaginal repairs until the patient has passed the child-bearing age.

Placenta previa, we believe, is best treated by cesarean section, except in cases of low implantation with slight bleeding and a cervix effaced and dilatable, assuring a speedy onset and rapid termination of labor after artificial rupture of the membranes. Patients with placenta previa, if the diagnosis is made with sufficient confidence from soft-tissue x-ray films and cystograms, may undergo cesarean section without corroborative vaginal examination. If the x-ray film does not offer enough proof of the abnormally situated placenta a sterile vaginal examination is done as near term as possible with the operating room prepared for abdominal delivery.

Premature separation of the placenta is usually managed with cesarean section after the patient has recovered from the initial shock. In an occasional case with a soft, dilatable cervix rupture of the membranes and a tight abdominal binder are employed.

Fibroids were a rare indication for cesarean section, accounting for only 4 cases in this study,

and these presented obstructing tumors to delivery from below. Myomectomy was rarely done with the section, and there were no Porro cesarean hysterectomies with fibroids as an indication.

Sixteen cesarean sections were done for severe toxemia and eclampsia, a low incidence that is due partly to the infrequency of toxemias in the past decade and also to the conservative management of these cases. There were 9 cases of severe pre-eclampsia and 7 of eclampsia in this group with no deaths. One patient with severe toxemia with abruptio placentae, however, died of uremia and cortical necrosis of the kidneys. In the patient with severe toxemia who has reached a quiescent

stage and in whom delivery must be effected as expeditiously as possible, if the cervix is not ripe for induction of labor, elective cesarean section is done preferably under local anesthesia with pentothal sodium intravenously, or with pentothal alone.

There were 6 cases of ruptured uterus, 2 traumatic from attempted delivery outside the hospital and 4 that followed rupture of scars of previous cesarean sections. The treatment was always hysterectomy.

Four patients with rheumatic heart disease were decompensated at the time of operation and were managed by cesarean section with considerable misgiving and with a fatal outcome in 3 cases. Medical consultation had offered an unfavorable prognosis whatever course was selected and suggested possible amelioration of symptoms if the fetus were removed through the abdominal route with the least possible trauma under local anesthesia. The severely decompensated cardiac patient in the last trimester will always present a difficult problem with a poor prognosis no matter how the pregnancy is terminated.

#### OPERATORS

Four hundred and forty cases were done by the residents and interns, and 521 by the visiting staff. Paradoxically, there were only 3 deaths among

the cases done by the residents, a mortality of 0.7 per cent, whereas 20 patients who were operated upon by the visiting staff died, a mortality of 4 per cent. The discrepancy in mortality rates is evidence that the more experienced group assumed the responsibility of the poorer risks. However, this fact should not detract appreciably from the excellent record of the resident staff.

### MORBIDITY

The incidence of morbidity is presented in Table 4. A temperature of 100.4°F or higher on any two days of the puerperium, exclusive of the first twenty-four hours, was considered evidence of infection. The morbidity in the entire series was 26.6 per cent. Since the introduction of the sulfonamide drugs and penicillin this has been reduced to 10 per cent. The rate for elective cesarean section was 15 per cent in contrast to 37 per cent for the emergency operation. The morbidity rate in the few cases in which the Waters extraperitoneal

TABLE 4 Morbidity

DURATION OF FEVER	NO. OF CASES	INCIDENCE
days		%
0	706	73.5
1	98	10.2
2	70	7.3
3	25	2.6
4	62	6.4
5 or more		

operation was done was 40 per cent. The patients who had suffered considerable blood loss were more inclined to show evidence of infection postoperatively, averaging 45 per cent. Ruptured membranes over twelve hours or labor over twenty-four hours caused temperature elevations in 40 per cent of the cases. Prophylactic administration of penicillin and the sulfonamides in cases potentially infected in which cesarean section is anticipated, together with the liberal use of transfusion to compensate for blood loss, is lowering these figures to a great extent.

### TYPE OF OPERATION

Most of the cesarean sections were done by the low cervical technic, which showed an increase from 79 per cent reported by Duncan and Doyle<sup>1</sup> to 91 per cent in our series (Table 5). The transverse incision was preferred because it was confined more readily to the lower uterine segment and provided less operative difficulty in repeat sections. The classic incision, which waned in popularity from a 20 per cent incidence in the previous decade to 6 per cent, is now performed only when the lower-segment operation is not

feasible because of varices, fibroids or inextensible adhesions preventing access to the lower segment.

The Waters extraperitoneal operation was done in 10 frankly infected cases, with no deaths. If patients who may require cesarean section are given prophylactic penicillin and sulfonamide therapy while undergoing a test of labor, the indications for the Waters technic are considerably decreased.

The Porro cesarean hysterectomy was done in 20 cases. Six cases of ruptured uterus were treated

TABLE 5 Types of Operation

OPERATION	NO. OF CASES	INCIDENCE
Low cervical	874	91
Transverse (Kerr)	800	82
Longitudinal (Kroenig)	74	8
Classic	57	6
Extraperitoneal (Waters)	10	1
Porro	20	2

in this manner. The other 14 were cases of uncontrollable bleeding, which included 6 cases of placenta previa, 5 of couvelaire uterus following abruptio placentae, 2 of hemorrhage from post-partum uterine atony, and 1 of placenta accreta with the placenta adherent to a previous cesarean scar. There were no deaths from the Porro operation.

### ANESTHESIA

The types of anesthesia are presented in Table 6. Prior to 1941 the anesthetic of choice was nitrous

TABLE 6 Types of Anesthesia

ANESTHESIA	NO. OF CASES
Nitrous oxide, oxygen and ether	537
Open ether	66
Spinal	323
Local	6
Pentothal	4

oxide, oxygen and ether. Since 1941 spinal anesthesia has been used almost routinely except in bleeding cases. Sodium pentothal was administered intravenously in 4 cases of severe toxemia. Local anesthesia was employed in only 6 cases, but its use should be adopted more generally since it is the safest of all anesthetics. Anesthesia for cesarean section is now administered only by the qualified men of the anesthesia service.

### FETAL MORTALITY

There were 72 fetal deaths making a gross fetal mortality of 7.5 per cent (Table 7). Discounting the cases of stillbirth due to ruptured uterus and hemor-

age, the rate was 3 per cent. Of the neonatal deaths the majority were due to prematurity, especially in the patients with placenta previa. In the cases in which the cesarean section was repeated

TABLE 7 *Fetal Mortality*

CAUSE	No OF DEATHS

Ruptured uterus	6
Abruptio placentae	20
Placenta previa	18
Neonatal death	25
Prematurity	12
Atelectasis	10
Cerebral injury	4
Erythroblastosis	1
Congenital abnormality	1

there were 9 neonatal deaths, a mortality of 15 per cent.

### MATERNAL MORTALITY

The causes of death are presented in Table 8. There were 23 maternal deaths, a mortality of 2.4 per cent, this is an improvement over the previous decade, in which the rate was 4.3 per cent. Of these 23 cases, 7 had been badly managed by private physicians, and the patients were in poor condition. These cases included 3 of separated placenta with the patient in shock and badly exsanguinated, 2 of placenta previa in which the patients had been allowed to bleed for a long time before the decision was made to send the patient to the hospital and 2 of cephalopelvic disproportion in which the patients had been in labor over forty-eight hours and in which several attempts at manual dilatation of the cervix and forceps delivery had been made unsuc-

Total	23	

cessfully. The mortality for the cases followed through the entire pregnancy was 1.6 per cent.

The relation of the deaths to the indications for cesarean section is presented in Table 9. There were 5 deaths among the patients with repeat cesarean section. Two of these were from spinal anesthesia, and 1 from aspiration of vomitus during inhalation anesthesia, all of which occurred before the present well trained anesthesia service assumed the respon-

sibility of this important phase of obstetrics. One patient died of secondary hemorrhage twelve hours after operation. The fifth death was from embolus (proved at autopsy) one hour after delivery (the only unavoidable death in the group).

Five deaths occurred among the patients with disproportion. Three died from sepsis, and 2 of these cases had been mismanaged outside the hospital. All these cases occurred before the days of the sulfonamides and penicillin. One patient, who died from hemorrhage on the twenty-third post-partum day, had had several episodes of moderate bleeding before the fatal hemorrhage and should have had a hysterectomy early in the post-partum period. There was 1 death from embolism in this group.

In the cases of placenta previa there were 4 deaths. One was from sepsis, 2 from hemorrhage, and 1 from lobar pneumonia before the days of the antibiotics.

There were six deaths from separated placenta. Four patients died from shock and hemorrhage, 1 from uremia and cortical necrosis on the third post-

TABLE 9 *Deaths in Relation to Indications for Cesarean Section*

operative day, and 1 from embolism on the fourteenth day.

Of the 4 patients with cardiac disease who underwent cesarean section while decompensated, 3 died. Two died of typical cases of cardiac decompensation (both elderly primiparas, aged forty-two and forty respectively), 1 in eight days and the other in six days. The third patient died in eleven days from an embolism.

### CONCLUSIONS

On the basis of these statistics certain axiomatic facts pertaining to cesarean section may be deduced.

Hemorrhage and sepsis are the most common causes of mortality from cesarean section.

Whole blood given early, rapidly and copiously is the only way to combat hemorrhage. Too often, transfusions are given too late, too slowly and in too small amounts.

Cesarean section must not be done in the presence of shock. Shock must first be treated as expeditiously as possible.

One must be sure there is no chance for secondary hemorrhage either from uterine atony or from improper hemostasis before the abdomen is closed.

Cesarean section has a distinct place in the treatment of toxemia and does not add to the risk especially if done under local or sodium pentothal anesthesia

There is no limit to the number of cesarean sections that a patient may undergo, provided sufficient attention is given to the uterine scar both before and at operation

The danger in cesarean sections after rupture of the membranes and prolonged labor is sepsis. Therefore, every patient in whom cesarean section is probable, when given a test of labor should receive sulfonamides and penicillin prophylactically after the first twelve hours. In the frankly infected cases the extraperitoneal operation should be done

Cesarean section in cardiac cases offers no advantage over delivery through the pelvis and should not be done unless there is some other indication.

Anesthesia for cesarean section must be administered by a trained anesthetist, especially if one decides to use spinal anesthesia

With proper attention to these suggestions the mortality for cesarean section should be kept below 1 per cent

## HOSPITAL ADMINISTRATION AS A CAREER

E. M. BLUESTONE, M.D.\*

NEW YORK CITY

THE doctor's prescription has been one of the most important characteristics of the medical profession throughout the ages. It is as much the symbol of the medical profession as the mortar and pestle of the profession of pharmacy. Men doubtless prescribed in the dark before they elaborated the wherewithal to diagnose. The earlier the prescription, the greater appears to have been the element of chance with which our professional ancestors approached their patients. It is still the rod and the staff that comfort the patient, if not the practitioner. Even the placebo carries a world of meaning. Nothing justifies a fee like a prescription, and that is why the practitioner in search of the Holy Grail avoids medicine that is odorless, colorless and tasteless. One need only ponder over the slowness with which the pharmacology laboratory is arriving in the hospitals of today to understand the tenacity of sentiment versus science in prescription writing. The pharmacy is still patronized more for the products of the nostrum vendor and the quack than for the tested remedies of the man of science. The incantations of primitive man have their unhappy survival in the hit-or-miss prescriptions that belie our scientific pretensions.

Those who are still in the academic stages, and those who are serving clinical apprenticeships, know much better about the needs of the patient than their ancestors did. Modern practitioners of medicine are not so helpless and need not tolerate the shotgun methods of yesterday. If they do, it must be for a compelling reason, and I suggest that the dilemma be thoughtfully weighed.

Though the principles and practice of social medicine are not yet taught in medical colleges and hospitals with the pedagogic energy that is expended on prescription writing, one cannot help becoming aware of its arrival, its staying power and its influence on this dilemma. Our descendants will be more keenly aware of its possibilities for good than we can be at present. Since we are confronted with this humanized concept of medical practice, we cannot help taking notice of it and should want to know more about it. For those who have aptitude for the practice of social medicine and are so constituted that they can find joy in it, new and bright horizons will appear. The doctor, in the role of social agent, has limitless possibilities. If, working in such an enlightened kind of medical practice, he finds a substitute to replace the fee-for-prescription method of compensation that dominates the individual practice of medicine (which, incidentally, must struggle with such a handicap to be scientific) he opens the doors of a room that is dimly lit and lets the sunshine in so that others, too, can benefit.

In recent decades of world upheaval, we have been taught many severe lessons that have brought home to us the broad concept of social medicine, in which the prescription is only one of many symbols. The practitioner is already beginning to merge his personality into this new concept, and he is doing it as an instrument of a sympathetic society. Before this development can proceed, however, someone must assume leadership and help to plan, build, organize and administer, to the end that we shall have worthy officership in this new army of practitioners. These officers should be located at general

\*Director, Montefiore Hospital

headquarters, as well as in field headquarters, and the hospital qualifies admirably for either purpose. According to the new trends, the hospital is beginning to emerge as the hub of medical activity radiating from its central diagnostic and therapeutic facilities, and serving the community as an integral part of it, are the outpatient department, the doctors' office building (which will bring the doctor closer to his workshop), the department for continued care (which will discharge a debt that has been owing for some time to the long-term patient), the department of psychiatry, the department of tuberculosis (if this illness is not brought under control sooner — and even if it is), the group-practice unit (for an insured group of patients), the health center, the convalescent unit and the preventorium. Hospital care in the home will also radiate from such a center and serve patients extramurally on an extension basis so that they will be cared for at all times and in all places, comprehensively. The practitioner never had a better friend than this kind of center promises to be, nor did the sick. He must, therefore, familiarize himself with its possibilities for good in his professional life as a man of science, unless he wants to remain a prescription writer who continues to practice uncritically, forever, what he was taught to prescribe in medical school. Each one of the activities revolving around the hospital calls for executive talents of a high order, and each one is beckoning to the young house-staff graduate who has the imagination, the vision and the other qualities of leadership to take advantage of such opportunities.

Hospital administration as a career is not limited to medical men, but medical men possess advantages, whereas laymen must overcome handicaps in this kind of executive work, which calls for considerable medical knowledge as well as social insight. It has been said that the hospital executive must also be a good "businessman" and that the layman has the edge on the physician in this respect, but this requirement is more apparent than real and is not based on actual experience in the hospitals of this country. This is not to deny that good business judgment is helpful to the medical executive. In the long run, however, medical knowledge, medical objectives and medical opinion must be sought and considered.

There was never a time in medical history when the need for qualified medical executives in hospitals and elsewhere was greater than it is today. The opportunities for qualified men are endless, with new areas for creative work opening up daily, and the conditions of service are favorable. The medical executive is able to live a full and useful life, with credit to himself and his family. Riches are not to be sought in the professions in any case. Medical executives live in comfortable material circumstances, unworried by profit motives, and are assured a continuous income, which is seldom inade-

quate. The reduction of the overhead costs, which must be balanced against income, is only one comparative aspect of the matter.

It is said, of course, that the medical executive must surrender some of his independence when he becomes subservient to a board of trustees, — of whom, by the way, he is always a few jumps ahead in the program if he is worth his salt, — but independence to do what? To be legally free, as some are, to practice alone while the four walls, like dead men, tell no tales? To charge whatever the traffic will bear, as some do, while rebelling inwardly at the necessity for such compromises with the high code of medical ethics taught in medical schools? The practitioner will become the man of science that he deserves to be, and ought to be, when he or his colleagues will stand up and, through the kind of leadership here outlined, challenge the prevailing method of distributing medical care.

No doubt the practitioner, be he physician, surgeon or specialist, is attracted by the more dramatic forms of medical practice. As a medical executive, I envy the surgeon his joy when a patient on whom he has performed a successful laparotomy is discharged cured, after a short stay in the hospital, though an occasional patient may be lost. His results are more tangible in terms of space and time. But the cures of the medical executive reach out into a wide area of space and cover a long period. Though the results of his planning are not so immediately visible, or heartwarming, to the medical executive they reach far more people and their effects often make medical history. Without the planner, the practitioner toils laboriously in vain.

Medical executive work, by its very nature, brings the rewards of good companionship. Work on the frontier is always exhilarating to the pioneer, and he is forever rubbing elbows with others whose outlook on medical life is similar to his own. The related specialties are close. Social service becomes a prize prescription, with a wealth of vital ingredients — none of which, by the way, act mysteriously. Social medicine, which is the practice of medicine in relation to all the social forces that influence our lives, is a more intelligible and more life-giving concept than the limited form of medical practice that preceded and survived the advent of the social sciences. It should therefore be cultivated for its worth and should attract qualified leadership.

The opportunities for full-time executive medical service are many, and these are knocking at the doors of young physicians who are prepared to put in an additional apprenticeship in administrative medicine. Schools for hospital administration, with mixed lay and medical student bodies, have come into vogue in recent years and provide an academic year of university training on a graduate level, followed by an administrative internship of a year leading to a master's degree. The alternative to this

kind of formal preparation is an apprenticeship to a good teacher, under whom the student qualifies in the school of experience. A combination of both is undoubtedly the best kind of preparation. In any case, the student should allow five years for seasoning from the time of his graduation from the house staff of a hospital before seeking an independent executive position where much will depend on his maturity of judgment. Apprenticeship of this kind, unlike the advanced residencies in clinical medicine, pays a good living wage, and the rest can safely be

charged up to investment by an ambitious and self-confident student. Dividends start flowing early because the opportunities are so great.

For the future medical executive there opens up a world of opportunity and one that remains unmatched in the learned professions. For those whose aptitudes and preferences are in clinical medicine, there are additional worlds to conquer, but these worlds will be conquered faster and more completely through a proper distribution of personnel where each can do the most good in his own way.

## MEDICAL PROGRESS

### CHEMOTHERAPY OF NEOPLASTIC DISEASE

#### II Trends in Experimental Cancer Therapy

DAVID A. KARNOFSKY, M.D.\*

NEW YORK CITY

The cancer chemotherapist, in the absence of a fundamental philosophy or a satisfactory approach to his problem, is an eclectic, borrowing ideas and discoveries from the more advanced or at least the more fruitful scientific disciplines. The range of his interests and the nature of his approach are shown in the number of chemicals and groups of substances under study. These agents are, for the most part, chiefly of interest in a historical and immediate sense for man, if not all, will ultimately be discarded. Until a fundamental discovery appears, each year will see new agents greeted with enthusiasm, and each decade will see some of these compounds through a cycle of interest and sometimes enthusiasm — created in various ways — and then active rejection or passive disuse. These cycles, of course, leave a residuum of basic and useful information that will make subsequent work more efficient and critical and from which, some day, important contributions may develop. In the following paragraphs the major current trends in cancer chemotherapy are reviewed, with emphasis on substances under recent clinical trial.

#### BIOLOGIC PRODUCTS

##### *Bacteria, Molds and Protozoa*

**Coley's mixed toxins.** In 1892, acting on the reported clinical observations that attacks of erysipelas in patients with inoperable cancer were sometimes associated with permanent or temporary tumor regressions, Coley began to use killed cultures of virulent streptococci isolated from patients with erysipelas in the treatment of cancer. Subsequently, *Bacillus prodigiosus* (*Serratia marcescens*) was added

to the cultures, since this organism was believed to increase the virulence of the streptococci. Vaccines of this general type were used for a number of years in many parts of the world. In spite of the occasional favorable reports, the therapeutic activity of the vaccine appears to have been inconstant and unpredictable, and its use was gradually abandoned. Apparently, an important factor in preventing an acceptable or definitive evaluation of Coley's toxins lay in the variability of the preparations used and the different dosages and technics of administration. In an effort to revive interest in this form of treatment, recent historical reviews of Coley's toxins have appeared.<sup>37, 38</sup> These reviews do not enhance the status of the agent, or present any compelling reason for its further clinical use. As an approach to cancer chemotherapy, Coley's work has anticipated and encouraged the modern investigations on purified bacterial toxins.

**Shear's polysaccharide.** In 1931 Gratia and Linz<sup>39</sup> reported that bacterial filtrates produced hemorrhages in a transplanted tumor in the guinea pig. Zahl and his group<sup>40-42</sup> tested a large number of bacterial filtrates and suspensions against Sarcoma 180 in mice, and found that the hemorrhage-producing substances occurred chiefly in gram-negative organisms, and were probably endotoxin antigens. Under the direction of Shear<sup>43</sup> an extensive cooperative study has been in progress on the isolation, characterization and mechanism of action of the hemorrhage-producing substance found in *B. prodigiosus* filtrates. The active material is homogeneous by electrophoresis and ultracentrifugation.<sup>43, 44</sup> Chemically, it appears to be composed chiefly of polysaccharides with small amounts of phospholipid and nitrogen in several unidentified

\*Associate Sloan Kettering Institute for Cancer Research fellow in medicine Memorial Hospital Center for Cancer and Allied Diseases fellow Jane Coffin Childs Memorial Fund for Medical Research

orms<sup>45</sup> The material is not inactivated by trypsin it is extremely toxic to mice, a dose of 0.01 mg (about 0.5 mg per kilogram of body weight) in mice weighing 20 gm will produce a significant mortality. It is antigenic and after repeated injections, larger doses are needed to produce a toxic effect. In mice a toxic dose of the polysaccharide will cause a fall in body temperature<sup>46</sup>, in rabbits and mice it is a pyrogenic agent.<sup>47</sup>

The purified agent on parenteral administration, at doses not injurious to the normal tissues, will induce hemorrhage within a few hours, followed by necrosis and partial regression of transplanted and spontaneous mouse tumors.<sup>48</sup> Mitotic activity in the tumor disappears one and a half hours after the injection of a maximum tolerated dose, the nuclei swell and then become pyknotic.<sup>49</sup> There is a fall in the blood flow in the tumor capillaries, numerous petechiae appear, and the blood flow finally ceases.<sup>50</sup> Several days later new capillaries begin to form at the periphery of the tumor with multiplication of the surviving tumor cells. The polysaccharide does not show any selective toxicity to cells in tissue culture.<sup>51</sup> The general interpretation of effect is that the polysaccharide acts by producing a "shock-like" state, the blood supply to the vulnerable capillaries in the tumor is decreased, and edema, hemorrhage and necrosis may then develop in the tumor. There is no satisfactory evidence of a direct toxic effect on the tumor cells.<sup>50</sup>

The purified polysaccharide was first used clinically by Brues and Shear<sup>52</sup> on several different types of tumor in 4 seriously ill patients. The agent, in very small doses, produced a high fever, leukocytosis and a fall of blood pressure, frequently to shock levels. Hemorrhage into the tumor and occasionally a decrease in tumor size were observed. Holloman<sup>53</sup> and Oakey<sup>54</sup> have reported their experiences on a total of 17 cases with a variety of tumors. The treatment appears to be hazardous, but the tumors sometimes regress and occasional temporary clinical improvement develops. Shear's group states, however, that the purified polysaccharide is not considered suitable for general clinical use.<sup>18</sup>

**Crude penicillin** Cornman<sup>55</sup> observed that crude penicillin was injurious in tissue cultures to several types of rat and mouse sarcomas at concentrations that did not damage normal fibroblasts. This selective effect was not found with purified penicillin.<sup>56, 57</sup> The penicillin impurity exerting this selective effect in tissue culture has not been identified.

Studies of the effects of a variety of mold filtrates and extracts on the neoplastic cell are now in progress.<sup>58, 59</sup> Cohen, Borsook and Dubnoff<sup>61</sup> tested a variety of micro-organisms by an *in vitro* technic for disclosing carcinoclastic microbial products, and they report that cultures of *Sporosarcina ureae* contain a substance injurious to tumor cells. Kidd<sup>60</sup> has reported that culture filtrates of *Aspergillus fumigatus*, presumably containing gliotoxin, were injuri-

ous to tumor cells *in vitro*, but this extract has not proved effective thus far against tumors *in vivo*.

**K-R** An endotoxin prepared from killed *Trypanosoma cruzi* (the causative agent of Chagas's disease), developed by Roskin<sup>61</sup> and Klyueva<sup>62</sup> and appropriately named K-R, has been reported to be effective in treating cancer in mice and man. In tumor-bearing mice infected with *T. cruzi*, Roskin observed a concentration of the organisms in the tumor, associated with destructive and regressive changes. Infections with *Borrelia duttoni* (*Spirochaeta duttoni*) (relapsing fever) and *Trypanosoma equiperdum* (dourine) were without effect on the tumors. Roskin, with the assistance of Klyueva, then prepared an endotoxin from *T. cruzi* that was also found to damage neoplastic cells. Regressions in Sarcoma 180 and Ehrlich's carcinoma of mice and in the Flexner-Jobling carcinoma of rats were produced without injury to normal tissue. If tumor cells were soaked in a K-R solution prior to implantation in mice, they failed to "take." The active material was water soluble, retained its activity after heating at 50°C for twenty minutes, but it lost its potency within ten to twelve days when kept at 1°C in the liquid state.

In 1941 K-R was first used in the treatment of patients with cancer. The subcutaneous, intramuscular or intratumoral injection of K-R caused cancers to disintegrate. Five out of 10 carcinomas of the larynx, 3 carcinomas of the cervix and 3 out of 5 carcinomas of the breast regressed remarkably under treatment. The beneficial effects varied directly with the dosage, large doses, however, caused a high temperature, and treatment was temporarily stopped. One unit was standardized as 1,000,000 *T. cruzi* organisms, and a course totaling 755 units has been given to a single patient.

The Russian reports of the remarkable results achieved with K-R therapy prompted confirmatory studies in this country. Hauschka<sup>63-65</sup> has carried out the most extensive work, using eight different strains of *T. cruzi*, including the one used by Roskin, against five types of tumor in mice. Mice infected with *T. cruzi* showed consistent retardation of tumor growth and occasional tumor regressions, but this was related to the virulence of the strain and the lives of the mice were not prolonged. The parasites did not concentrate in the tumors, as stated by Roskin, in fact, the cancer cells proper were only rarely parasitized, whereas the visceral organs and skeletal muscles were heavily infected. One virulent strain produced suppression of tumor growth coincident with weight loss and death eight to thirteen days after inoculation, but if the infection was checked with the quinoline derivative, Bayer 7602, tumor growth was resumed. Killed cultures and lysates of *T. cruzi* were without effect on tumor growth in mice,<sup>64, 65</sup> and Cohen, Borsook and Dubnoff<sup>61</sup> were unable to demonstrate any effect of *T. cruzi* on mammary carcinoma and Brown-Pearce

kind of formal preparation is an apprenticeship to a good teacher, under whom the student qualifies in the school of experience. A combination of both is undoubtedly the best kind of preparation. In any case, the student should allow five years for seasoning from the time of his graduation from the house staff of a hospital before seeking an independent executive position where much will depend on his maturity of judgment. orms<sup>45</sup> The material is not inactivated by trypsin it is extremely toxic to mice, a dose of 0.01 mg (about 0.5 mg per kilogram of body weight) in mice weighing 20 gm will produce a significant mortality. It is antigenic and after repeated injections, larger doses are needed to produce a toxic effect. In mice a toxic dose of the polysaccharide will cause a fall in body temperature<sup>46</sup>, in rabbits and mice it is a pyrogenic agent.<sup>47</sup>

The purified agent on parenteral administration, at doses not injurious to the normal tissues, will induce hemorrhage within a few hours, followed by necrosis and partial regression of transplanted and spontaneous mouse tumors<sup>48</sup>. Mitotic activity in the tumor disappears one and a half hours after the injection of a maximum tolerated dose, the nuclei swell and then become pyknotic<sup>49</sup>. There is a fall in the blood flow in the tumor capillaries, numerous petechiae appear, and the blood flow finally ceases<sup>50</sup>. Several days later new capillaries begin to form at the periphery of the tumor with multiplication of the surviving tumor cells. The polysaccharide does not show any selective toxicity to cells in tissue culture<sup>51</sup>. The general interpretation of effect is that the polysaccharide acts by producing a "shock-like" state, the blood supply to the vulnerable capillaries in the tumor is decreased, and edema hemorrhage and necrosis may then develop in the tumor. There is no satisfactory evidence of a direct toxic effect on the tumor cells<sup>50</sup>.

The purified polysaccharide was first used clinically by Brues and Shear<sup>52</sup> on several different types of tumor in 4 seriously ill patients. The agent, in very small doses, produced a high fever, leukocytosis and a fall of blood pressure, frequently to shock levels. Hemorrhage into the tumor and occasionally a decrease in tumor size were observed. Holloman<sup>53</sup> and Oakes<sup>54</sup> have reported their experiences on a total of 17 cases with a variety of tumors. The treatment appears to be hazardous, but the tumors sometimes regress and occasional temporary clinical improvement develops. Shear's group states, however, that the purified polysaccharide is not considered suitable for general clinical use<sup>16</sup>.

**Crude penicillin** Cornman<sup>55</sup> observed that crude penicillin was injurious in tissue cultures to several types of rat and mouse sarcomas at concentrations that did not damage normal fibroblasts. This selective effect was not found with purified penicillin<sup>56, 57</sup>. The penicillin impurity exerting this selective effect in tissue culture has not been identified.

Studies of the effects of a variety of mold filtrates and extracts on the neoplastic cell are now in progress<sup>58, 59</sup>. Cohen, Borsook and Dubnoff<sup>60</sup> tested a variety of micro-organisms by an in vitro technic for disclosing carcinoclastic microbial products and they report that cultures of *Sporosarcina ureae* contain a substance injurious to tumor cells. Kidd<sup>60</sup> has reported that culture filtrates of *Aspergillus fumigatus*, presumably containing gliotoxin were injuri-

ous to tumor cells in vitro, but this extract has not proved effective thus far against tumors in vivo.

**K-R** An endotoxin prepared from killed *Trypanosoma cruzi* (the causative agent of Chagas's disease), developed by Roskin<sup>61</sup> and Klyueva<sup>62</sup> and appropriately named K-R has been reported to be effective in treating cancer in mice and man. In tumor-bearing mice infected with *T. cruzi*, Roskin observed a concentration of the organisms in the tumor, associated with destructive and regressive changes. Infections with *Borrelia duttoni* (*Spirochaeta duttoni*) (relapsing fever) and *Trypanosoma equiperdum* (dourine) were without effect on the tumors. Roskin, with the assistance of Klyueva, then prepared an endotoxin from *T. cruzi* that was also found to damage neoplastic cells. Regressions in Sarcoma 180 and Ehrlich's carcinoma of mice and in the Flexner-Jobling carcinoma of rats were produced without injury to normal tissue. If tumor cells were soaked in a K-R solution prior to implantation in mice, they failed to "take". The active material was water soluble, retained its activity after heating at 50°C for twenty minutes, but it lost its potency within ten to twelve days when kept at 1°C in the liquid state.

In 1941 K-R was first used in the treatment of patients with cancer. The subcutaneous, intramuscular or intratumoral injection of K-R caused cancers to disintegrate. Five out of 10 carcinomas of the larynx, 3 carcinomas of the cervix and 3 out of 5 carcinomas of the breast regressed remarkably under treatment. The beneficial effects varied directly with the dosage, large doses, however, caused a high temperature and treatment was temporarily stopped. One unit was standardized as 1,000,000 *T. cruzi* organisms, and a course totaling 755 units has been given to a single patient.

The Russian reports of the remarkable results achieved with K-R therapy prompted confirmatory studies in this country. Hauschka<sup>63-65</sup> has carried out the most extensive work, using eight different strains of *T. cruzi*, including the one used by Roskin, against five types of tumor in mice. Mice infected with *T. cruzi* showed consistent retardation of tumor growth and occasional tumor regressions, but this was related to the virulence of the strain and the lives of the mice were not prolonged. The parasites did not concentrate in the tumors, as stated by Roskin, in fact the cancer cells proper were only rarely parasitized, whereas the visceral organs and skeletal muscles were heavily infected. One virulent strain produced suppression of tumor growth coincident with weight loss and death eight to thirteen days after inoculation, but if the infection was checked with the quinoline derivative, Bayer 7602, tumor growth was resumed. Killed cultures and lysates of *T. cruzi* were without effect on tumor growth in mice<sup>64, 65</sup> and Cohen, Borsook and Dubnoff<sup>61</sup> were unable to demonstrate any effect of *T. cruzi* on mammary carcinoma and Brown-Pearce

carcinoma by tests in vitro Malisoff,<sup>66</sup> however, reported that by means of K-R preparation he produced complete regression of 55 per cent of tumors (Sarcoma 180 and a spontaneous mammary carcinoma) in mice, but his work has been severely criticized.<sup>66</sup> In view of the general failure to confirm the laboratory aspects of Roskin and Klyueva's work, clinical trials with K-R are not indicated.

### *Urine and Tissue Preparations*

*H 11* H 11 is an extract of normal human urine reported to contain growth-inhibiting substances.<sup>67</sup> One group of workers has found that it slowly but ultimately inhibited the growth of the Twort carcinoma in mice,<sup>67</sup> but others were unable to demonstrate any therapeutic effect on mouse tumors.<sup>68, 69</sup> Since 1941, H 11 has been used in England for the treatment of inoperable carcinoma, but the remarkable therapeutic effects attributed to it have not been confirmed.<sup>70</sup>

*Myelokentric acid* Miller, Wearn and Heinle,<sup>71</sup> in 1939, described substances obtained from the urine of leukemic patients that induced stimulation of the myeloid and lymphoid systems in laboratory animals. Subsequent study by Heinle et al.<sup>72</sup> led to the conclusion that a substance can be extracted from the urine of patients with chronic myelogenous leukemia that will induce myeloid metaplasia in guinea pigs. The substance responsible for this effect appeared to be protein in nature.

On the other hand, a more complicated situation is suggested by Turner and Miller.<sup>73</sup> In the urine of patients with chronic myelogenous leukemia, a substance that produced myeloid metaplasia was obtained, whereas, in chronic lymphatic leukemia, the urine extract induced lymphoid metaplasia. These substances were named myelokentric and lymphokentric acid, respectively. In Hodgkin's disease and monocytic leukemia an intermediate effect in guinea pigs was obtained, and in these diseases the urine was found to contain a mixture of myelokentric and lymphokentric acids. Liver extracts contained both fractions. Extracts of myeloid leukemic tissue produced myeloid metaplasia, and lymphoid leukemic tissue, lymphoid metaplasia, tissue extracts from patients with Hodgkin's disease tissue caused a mixed reaction in the guinea pig.<sup>74</sup>

Miller, Herbut and Jones<sup>75</sup> have treated 8 patients with lymphoblastic leukemia with crude myelokentric acid. They observed 13 partial remissions in these patients, and at autopsy the disease appeared altered by the treatment. They do not recommend this treatment because the preparation is crude, it is very difficult to obtain, and there is no standard dosage.

*Splenic extracts* For many years, splenic extracts and preparations containing spleen, such as "splendotheran" and "aristotrop,"<sup>71</sup> have been proposed for the treatment of cancer, and all have fallen

into disrepute. Recently, however, it was reported that a splenic extract induced tumor regressions in mice and definite improvement and tumor regression in 3 patients with carcinoma.<sup>76</sup>

*A C S* Human spleen has been used as an antigen in rabbits to produce an antiserum, the "antitumoral cytotoxic serum" or A C S. This substance has been proposed by Bogomolets<sup>77</sup> as a formidable adjunct in the treatment of many diseases, including cancer. In inoperable cancer, he has reported that its use may reduce pain, improve the general condition of the patient, cause metastases to regress and sometimes prolong life. A C S made from mouse spleen will inhibit tumor transplants in mice, and rat A C S will inhibit the growth of the Walker rat Sarcoma 319 in vitro.<sup>78</sup>

Two clinical reports on A C S have appeared in this country.<sup>79, 80</sup> In a preliminary report on 106 cases, Davis<sup>79</sup> observed occasional relief of pain, gain in weight, increase in appetite and a sense of well-being. One patient with myeloid leukemia showed a fall in white-cell count with each course of treatment. A C S, however, could not be shown to prolong life. The usual course of treatment was 0.5 cc of the serum on the first, 1 cc on the fourth and 1.5 cc on the seventh day, courses were generally repeated every six weeks. Skapier<sup>80</sup> used the same dosage schedule in patients with Hodgkin's disease, and he observed a decrease in the sedimentation rate in 10 and a gain in weight in 12 out of 22 patients. There was no significant regression in enlarged lymph nodes. A C S does not appear to have any specific action in neoplastic disease, but Bogomolets's approach is of considerable interest.

Boylard<sup>81</sup> fed tumor-bearing mice various muscle extracts. The most effective inhibition of tumor growth was produced by extracts containing ethanolamine or cadaverine hydrochloride. Mouse carcinoma 2146 mixed with histone or protamine prior to inoculation showed a definite but transient decrease in growth rate, whereas human plasma or egg albumen did not have this effect.<sup>82</sup> The pentose nucleotides were injected into mice implanted with methylcholanthrene sarcomas, adenylic and guanylic acids inhibited tumor growth but also caused amyloidosis, cytidylic acid had little effect, and uridylic acid stimulated tumor growth.<sup>83</sup> Several dipeptides and d,l-dipeptides and polypeptides were found to have no effect on the growth of mouse and rat tumors.<sup>84</sup>

### *Vitamins*

The accessory food substances have been examined for their role in cancer growth, either by giving an excess of the vitamin or by producing a specific vitamin deficiency. A deficiency may be produced by dietary restrictions or the administration of specific antimetabolites.

*Biotin* As a result of the demonstration that biotin was essential for animal growth and that avi-

in, a protein contained in egg white, antagonized avidin, Laurence<sup>85</sup> suggested that avidin might be useful in the treatment of cancer. Mice on a biotin-deficient diet and mice fed large amounts of avidin showed no decrease in the rate of tumor growth.<sup>86, 87</sup> The feeding of large amounts of egg white to a total of 12 patients with cancer produced no clinical evidence of a biotin deficiency and no alteration in the course of the disease.<sup>88, 89</sup>

**Paraminobenzoic acid (PABA)** The influence of paraminobenzoic acid on chronic leukemia was examined by Zarafonitis et al.<sup>90</sup> It was given orally to 10 patients with chronic leukemia in doses of 2 to 4 gm every two hours, so that a blood level of 10 to 30 mg per 100 cc, and frequently higher, was maintained. This dose produced a fall in white-cell count, usually after two or three weeks of treatment. When treatment was discontinued the white-cell count promptly rose. While the drug was being given, some of the patients showed a partial clinical remission, which was slight and transient. The effects were more striking in chronic myelogenous than in chronic lymphatic leukemia. There is no suggestion that PABA has a significant therapeutic effect in leukemia. Bichel,<sup>91</sup> on the other hand, has reported that PABA will raise the white-cell count in leukemia.

**Pyridoxine** The growth of the Flexner-Jobling carcinoma in rats and 2 different transplantable tumors in mice was decreased on a pyridoxine-deficient diet.<sup>92</sup> A potent pyridoxine antagonist, desoxypyridoxine, when given to mice on a pyridoxine deficient diet, inhibited the growth of a transplanted lymphosarcoma.<sup>93</sup>

**Teropterin** Lewisohn and his group<sup>94-96</sup> reported that spleen extract, extracts of the spleens from mice cured of Sarcoma 180 ("healed-spleen extract"), yeast extract, pearled barley extract, inositol and *Lactobacillus casei* factor (pteroyl-triglutamic acid, or teropterin), cured an appreciable percentage of mice inoculated with Sarcoma 180. The "healed-spleen extract" and pteroyltriglutamic acid also induced regressions in spontaneous mammary tumors in mice. Pteroylglutamic acid did not cause tumor regression.<sup>97</sup> Several other laboratories were unable to confirm these results,<sup>98, 99</sup> and there is no substantial laboratory evidence that pteroyltriglutamic acid has any influence on tumor growth.

In the past five years spectacular advances have been made in the chemistry and pharmacology of the folic acid compounds, pteroylglutamic acid and its conjugates.<sup>100</sup> Pteroylglutamic acid and pteroyltriglutamic acid (teropterin) produce hematologic remissions in pernicious anemia, nutritional macrocytic anemia and sprue.<sup>101</sup> In laboratory animals no significant qualitative differences in the pharmacologic actions of the pteroylmonoglutamic and triglutamic acid forms have been described.

On the basis of Lewisohn's work, Farber et al.<sup>102</sup> studied the effects of pteroyldiglutamic and triglu-

tamic acid on a series of 90 patients with a variety of neoplastic diseases. They found that these agents given intravenously or intramuscularly had no immediate or delayed toxicity or unpleasant side-effects. On the basis of their clinical experience, they recommended a daily dose of 20 mg. Patients were reported to feel better, showed an increase in energy, appetite and sense of well-being, and a diminution in apprehension and pain. Furthermore, in some of the treated cases, the tumors showed histologic changes that could be attributed to therapy. Lehy et al.<sup>103</sup> claimed that teropterin reduced the narcotic requirements of patients with inoperable cancer. Teropterin is now being sold as a palliative agent in cancer. It is therefore important to note that the therapeutic effects ascribed to teropterin are couched in such tenuous and devious terms that they defy critical analysis. In the absence of reproducible and consistent objective evidence of effect on neoplastic disease, teropterin cannot be regarded seriously as a chemotherapeutic agent against cancer.

Several folic acid antagonists have been prepared.<sup>104</sup> Meyer,<sup>105</sup> in a preliminary report, studied the effect of two of these compounds on acute leukemia. He observed a transient remission in 3 out of 5 cases. More recently, an extremely toxic folic acid derivative, 4 amino-pterovylglutamic acid (aminopterin), has been under study. This material does not behave in animals like a typical folic acid antagonist, and it appears to have toxic properties of its own. It has recently been reported to induce temporary remissions in acute leukemia in children.<sup>106</sup>

### Hormones

Studies of the therapeutic effects of the sex hormones on tumors arising in sex-linked organs have been conducted almost entirely in man. It is extremely difficult to obtain transplantable animal tumors that are sensitive to the influence of sex hormones, androgens<sup>107</sup> and estrogens<sup>108</sup> have little influence on the growth of the commonly used mouse tumors. In man, the therapeutic effect of the several types of estrogenic hormones on carcinoma of the prostate is attributed to estrogenic activity per se. It is of interest that alpha-bromo-alpha, beta, beta-triphenylethylene, a relatively weak estrogen as compared with stilbestrol, is stated to be unusually effective in the treatment of prostatic carcinoma.<sup>109</sup>

The adrenocortical hormones, which are involved in the metabolism of lymphatic tissue, have been shown to affect tumors of hematopoietic origin in mice. Heilman and Kendall<sup>110</sup> reported that 11-dehydro-17-hydroxycorticosterone (compound E), when given orally or parenterally, will produce a temporary regression of a transplantable lymphosarcoma in mice. This effect was more consistent in female mice or castrated male mice. Murphy and

Sturm<sup>111</sup> have found that treatment with the adrenocortical hormones or the pituitary adrenotropic hormone decreased the susceptibility of rats to a transplantable lymphatic leukemia. Law and Speirs<sup>112</sup> have described profound palliative effects, marked tumor regression and possibly some prolongation of life in mice with spontaneous lymphoid leukemia treated with adrenocortical extracts.

### CELL POISONS

There are a number of cellular poisons that, in the normal animal, are injurious to the more actively growing tissues (chiefly those of the blood-forming organs and the gastrointestinal tract). None of these agents have been shown to have a highly selective effect on cancer cells, per se, but certain tumors are temporarily more sensitive to these agents than the most susceptible of the normal tissues. Many of these agents, therefore, have been tested, and some are used extensively in the palliative treatment of cancer.

#### Nitrogen Mustards

The nitrogen mustards have the fundamental structure  $\text{ClC}_2\text{H}_4\text{N}^+\text{R}$ . The *bis* (beta-chloro-

ethyl) group is essential for the toxic characteristics of these agents (although certain minor modifications do not change its activity qualitatively), whereas the R group may be varied considerably without alteration of the essential characteristic pharmacologic actions of the molecule. Under physiologic conditions, active members of this group undergo rapid intermolecular rearrangement with the loss of a Cl to form an imine linkage. This is illustrated by the most common nitrogen mustard studied, methyl *bis* (beta-chloroethyl) amine hydrochloride  $\text{Cl}^-\text{C}(\text{CH}_2\text{CH}_2\text{Cl})_2\text{N}^+\text{CH}_3$ . The imine linkage

is the reactive part of the molecule, reacting with a great number of biologic substances. The pharmacologic action of the nitrogen mustards has been reviewed,<sup>113-118</sup> and their toxic actions from a physiologic<sup>116, 117</sup> and a pathologic point of view have been described.<sup>118, 119</sup> These compounds have been shown to produce cytologic damage,<sup>120-122</sup> mutations in *Drosophila*<sup>123</sup> and *Neurospora*<sup>124</sup> and selective effects on differentiating embryonic cells.<sup>125</sup> Their radiomimetic effects have been emphasized.<sup>114, 119</sup> Alterations in their chemical structure have produced marked changes in their pharmacologic activity.<sup>114, 115, 126, 127</sup>

The nitrogen mustards (and the closely allied sulfur mustards) exert an inhibitory effect on the growth of certain mouse tumors,<sup>128, 129</sup> prolong the life of mice with transmitted leukemia,<sup>26</sup> selectively inhibit the growth of the mouse Sarcoma 180 on the chorioallantoic membrane of the chick embryo<sup>28</sup> and exert a therapeutic effect on fowl leukosis.<sup>31</sup>

Burchenal and his associates<sup>28</sup> have examined the activity of a large number of nitrogen mustard analogues in prolonging the life of mice with transmitted mouse leukemia. They found that, in general, the quaternary ammonium compounds and the mono-(beta-chloroethyl) group compounds were inactive, whereas the bis (beta-chloroethyl) groups and bis (beta-bromoethyl) groups and diamine mustards with 4 beta-chloroethyl groups were active in prolonging life. There seemed to be a direct correlation of the radiomimetic toxic effect of a nitrogen mustard and therapeutic activity.

The clinical use of methyl-*bis* (beta-chloroethyl) amine hydrochloride (HN2) is discussed in the next section. Two nitrogen mustard derivatives, 1,3 propane diamine (NNN' N' tetrakis [2-chloroethyl]) (SK136) and 1,3 chloropropyl diamine (NNV' N' tetrakis [2-chloroethyl]) (SK137), which showed therapeutic activity against mouse leukemia, have been tested clinically.<sup>140</sup> Although these agents do not seem to produce as much nausea and vomiting as HN2, they cause dizziness and, occasionally, toxic psychoses, and therapeutically, they do not appear to be more effective than HN2.

#### Urethane

Ethyl carbamate is a relatively simple organic chemical with the following formula:

It had been known for many years to exert a suppressive effect on growth processes, but interest in this agent in relation to neoplastic disease is only of recent origin. In 1939 Lefevre<sup>141</sup> described abnormal development and retarded growth in seedlings exposed to ethylphenyl carbamate. Templeman and Sexton<sup>142</sup> undertook a systematic survey of the aryl carbamates and related substances as plant-growth inhibitors. They found isopropyl phenylcarbamate to be most effective, urethane and methyl carbamate were inactive. Haddow and Sexton,<sup>143</sup> therefore, examined the effects of carbamates on tumor growth in animals. Phenyl urethane and urethane proved to be equally effective in inhibiting the growth of spontaneous mammary tumors in mice and the transplanted Walker carcinoma 256 in rats and, among the members of the carbamate series tested, these substances were unique in having this effect. Subsequently, numerous confirmatory reports appeared, demonstrating the suppressive action of urethane on rat Sarcoma 39,<sup>134</sup> transplanted lymphatic leukemia in rats<sup>144</sup> and transplanted<sup>126, 128-129</sup> and spontaneous<sup>140</sup> leukemia in mice. The clinical application of urethane is discussed below.

In addition to the suppressing effect of the drug on tumor growth, the demonstration that urethane was carcinogenic also aroused interest. In 1943 Nettleship and Henshaw<sup>145</sup> reported that urethane administration induced pulmonary adenomas in mice, and a similar action has been recorded in

<sup>142</sup> An extensive literature now exists on the carcinogenicity of urethane. Larsen<sup>143</sup> has shown a remarkable specificity of the carcinogenic activity of ethyl carbamate, methyl carbamate is ineffective, and isopropyl carbamate has one-eighth and n-propyl urethane one-eightieth the carcinogenic activity of urethane.

Dustin<sup>144</sup> found that the parenteral administration of urethane to mice reduced mitotic activity and produced cellular degeneration in the intestinal mucosa. There was a decrease in the reticulocyte count in the peripheral blood of rabbits and a slight shrinkage in the size of lymph nodes, but injury to the bone marrow was not apparent.<sup>145</sup> Some hematopoietic injury can be produced in man with urethane,<sup>146</sup> and this may be due to the greater sensitivity of the human bone marrow as compared with that of lower animals. Urethane appears, therefore, to act as a mild cell poison *in vivo*. Vascular and parenchymal liver injury<sup>147</sup> and liver tumors<sup>148</sup> have been reported in rats treated with urethane.

#### Colchicine

Colchicine, an alkaloid obtained from the autumn crocus, is a mitotic poison, arresting cell division in the metaphase. It has been shown to induce temporary regressions of lymphoid tumors<sup>149</sup> and to prolong life in leukemic mice.<sup>150</sup> Ludford,<sup>149</sup> in a review of colchicine in the experimental chemotherapy of cancer, concludes that "regression of tumor growth subsequent to colchicine treatment is primarily the result of hemorrhages following the disruption of newly formed capillaries." The effect of colchicine on animal tumors is not significantly enhanced when the drug is given in combination with x-ray therapy,<sup>150, 151</sup> bacterial toxins<sup>152</sup> or 2-methyl-naphthoquinone<sup>153</sup> a substance with high vitamin K activity. A large number of colchicine derivatives have been tested against tumors, but none have shown any greater selective action than colchicine on neoplastic cells.<sup>149</sup>

Colchicine will induce an increase in mitotic figures in human tumors within twelve hours.<sup>154, 155</sup> Of 4 patients with advanced carcinoma treated with colchicine 2 died within a few days, apparently of colchicine poisoning, with fever, diarrhea, pancytopenia and bleeding tendencies. The remaining 2 survived to show some tumor regression.<sup>156</sup> The dosage varied from 12 to 22 mg in four or five days. It was concluded that although cancer cells are susceptible to colchicine, the concomitant toxic effect makes its use very hazardous. Colchicine was not found to be very effective in human leukemia,<sup>157, 158</sup> but the clinical trials were inadequate.

#### Podophyllin

Podophyllin, an extract of the dried rhizomes and roots of the mandrake plant, has been used for many years as a cathartic. It is composed of resins and an active principle, podophyllotoxin. When applied

locally, podophyllin is effective in the treatment of condyloma acuminata, and a similar therapeutic effect has been obtained with colchicine.<sup>159</sup> Podophyllin also blocked mitosis in the root tips of *Allium cepa*.<sup>160</sup> Podophyllin and podophyllotoxin have produced hemorrhage in mouse tumors.<sup>161</sup> In tissue cultures, podophyllin and, to a lesser extent, podophyllotoxin have a selective damaging effect on mouse tumor cells.<sup>162</sup> Podophyllin appears to be similar to colchicine in many of its toxic effects.

#### CARCINOGENIC AGENTS

In 1935 Haddow<sup>162</sup> demonstrated that potent carcinogens, including 1,2,5,6-dibenzanthracene and 1,2-benzpyrene, inhibited the growth of the Jensen rat sarcoma, 9,10-dimethyl-1,2-benzanthracene inhibited the growth of Sarcoma 180<sup>163</sup> and prolonged the life and, in some cases, cured mice with transmitted leukemia.<sup>164-166</sup> This agent produced leukopenia, but leukemic mouse cells were more sensitive to its action than the normal white cells. Engelbreth-Holm and Stamer<sup>167</sup> treated 11 patients with 9,10-dimethyl-1,2-benzanthracene. The agent was suspended in a 2.5 per cent solution in distilled water, and was given intravenously in single doses, as large as 1 gm daily, a total course consisting of 1 to 11 gm. The injection was well tolerated, but it produced fever, with some nausea. A brief clinical remission occurred in 1 of 5 patients with acute leukemia, a more prolonged remission developed in 2 patients with chronic myelogenous leukemia and 2 patients with chronic lymphatic leukemia showed definite improvement. The treatment was without effect in 2 patients with multiple myeloma.

Seligman et al.<sup>168</sup> have synthesized a number of noncarcinogenic hydrocarbons related structurally to the carcinogens. These agents were tested for chemotherapeutic activity in transmitted myeloid leukemia, mammary adenocarcinoma and fibrosarcoma in mice. None of these compounds or their carcinogenic analogues, prolonged the life of leukemic mice, but some compounds inhibited the growth of solid tumors.

The carcinogenic activity of another class of carcinogens, the aminostilbenes, was detected because it was first found to inhibit tumor growth.<sup>169</sup> Clinical trials have been started with 2'-methyl and 2'-chloro-4-dimethyl aminostilbene, but the difficulties of administration have, thus far, not been overcome.<sup>170</sup> Boyland<sup>170</sup> has commented on the fact that the carcinogenic agents are the ones that have proved to be most effective in the treatment of cancer, these include x-rays, Fowler's solution, urethane, estrogens and the nitrogen mustards (several mice treated chronically with this agent have developed tumors).<sup>171</sup>

Flory et al.<sup>24, 25</sup> tested a variety of substances against several strains of transmitted leukemia. *Potassium arsenite* and *benzene*<sup>172</sup> were effective in

prolonging the lives of leukemic mice, and one type of leukemia (L1394) was cured occasionally with benzene. Other organic arsenicals and benzene derivatives tested were less effective.

### RADIOACTIVE SUBSTANCES

X-rays or radioactive isotopes, which injure cells by their radiations, cannot be regarded as chemotherapeutic agents. Since one of the principles of isotope therapy, however, is the localization of the radioactive agents in certain tissues, the biochemical properties of the radioactive material are of great importance. The chemotherapist, therefore, has a fundamental role in this field. If he were to discover a substance that concentrated in certain types of tumors, it would be possible to make one or more of the atoms in this compound radioactive, and thereby specifically irradiate the neoplastic tissue. With this in mind, Bloch and Ray<sup>175</sup> have described methods for incorporating radioactive iodine in a variety of organic compounds.

Thus far, only radioactive elements have been tested as therapeutic agents in cancer. Radioactive phosphorus and iodine are in clinical use, and they are discussed below. Radioactive strontium concentrates selectively in areas of active bone formation, and it has been tried, with disappointing results, in the treatment of bone tumors.<sup>8</sup> Radioactive manganese ( $Mn^{52}$ ), with a half-life of six and a half days, is given as a colloidal sol and it is taken up by the reticuloendothelial system. It has been used in the treatment of diseases of the hematopoietic system and allied disorders.<sup>174</sup> Colloidal radioactive gold ( $Au^{198}$ ), with a half-life of two and three-quarter days, has been used more recently for this purpose.<sup>175</sup> Radioactive arsenic is an interesting isotope, but therapeutic trials with this agent have not yet been reported. Radioactive sodium ( $Na^{24}$ ), with a half-life of fourteen and four-fifths hours, is evenly distributed throughout the body, and it provides a method for controlled total body irradiation. It has produced effects similar to total body irradiation in mouse leukemia.<sup>176</sup> Hahn and Sheppard<sup>177</sup> have analyzed the properties of radioactive isotopes that would make them suitable for therapeutic use. It is inevitable that a large number of radioactive isotopes and compounds containing radioactive atoms will be characterized and evaluated in the treatment of cancer.

### MISCELLANEOUS COMPOUNDS

Literally thousands of miscellaneous substances have been tested or are now under test for selective effects on neoplastic cells. They are greatly diversified, and they cannot easily be brought together.

#### Dyes

Many dyes have been tested in the hope of finding one that concentrated selectively in tumors. Zahl and Waters<sup>178</sup> tested a series of colloidal dyes,

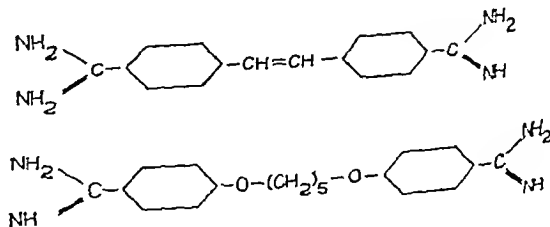

but could not demonstrate a selective uptake by tumor cells. The dye concentrated to some extent in the stroma surrounding the tumor, or at the interface of the viable and necrotic tissue. Boyland tested various derivatives of sulfonamides, and found that 4,4'-diaminodiphenyl sulfoxide, sodium sulfanilyl-sulfanilate<sup>21</sup> and 4,4'-diaminodiphenyl-ether<sup>179</sup> were most effective in temporarily inhibiting tumor growth in mice. The last compound, however, did not prove effective on clinical trial.<sup>21</sup> Lewis and Goland<sup>180,181</sup> tested a long list of acidic and other dyes by oral administration. Many of these stained tumors in mice and caused some retardation of growth, they did not prevent tumors from "taking" on transplantation or produce regressions in growing tumors.

#### Heptaldehyde

Strong<sup>182</sup> observed that heptyldehyde-sodium bisulfite, given in the proper dosage, caused regression and liquefaction in spontaneous mammary carcinoma in mice, although the regressions were rarely permanent. Boyland<sup>20,183</sup> tested a number of aldehydes, ketones and glucosides, and was able to report that, of these, citral and heptaldehyde inhibited the growth of spontaneous and transplanted tumors. Heptaldehyde sodium bisulfite methylsalicylate was selectively injurious in tissue culture to human and mouse mammary carcinomas and to rat lymphosarcoma.<sup>184</sup> Although heptaldehyde appeared to have an excellent record in the laboratory as an effective chemotherapeutic agent against neoplastic cells, it proved to be ineffective on clinical trial in 11 patients with metastatic mammary carcinoma<sup>185</sup> and in 3 patients with lymphoma.<sup>186</sup>

#### Stilbamidine

Stilbamidine (4,4'-diamidinostilbene) and a derivative, pentamidine (4,4'-(pentamethylenedioxy)dibenzamidine), are drugs that have proved effective in the treatment of kala-azar.<sup>178-189</sup> The formulas respectively, are as follows:

Because patients with kala-azar develop an elevated serum globulin, Snapper<sup>190,191</sup> used stilbamidine in multiple myeloma, a neoplastic disease in which a high serum globulin level is often present, with palliative results.

The mechanism of the action of stilbamidine in multiple myeloma is not definitely established, but several pertinent observations have been made. Popac<sup>192, 193</sup> has shown that stilbamidine reacts with nucleic acid to form a relatively inactive product, he suggests that stilbamidine acts by producing a dissociation of the protamine-ribonucleate complex, with the formation of protamine and a relatively insoluble stilbamidine-ribonucleate complex. Snapper et al<sup>194-196</sup> have described basophilic inclusion bodies that appeared in the myeloma cells after treatment with stilbamidine. These granules were shown to contain ribose nucleic acid. The inclusion bodies may develop one or two weeks after treatment has begun, persisting for many months. They occur most frequently in patients with disturbed protein metabolism — that is, in almost all patients with hyperglobulinemia and in most patients with normal serum globulin with Bence-Jones proteinuria, but in none of the patients with a normal serum globulin level without Bence-Jones proteinuria.<sup>196</sup>

Stilbamidine is made up as a di-isethionate salt, which is more stable and water soluble than the hydrochloride salt. The solution must be prepared immediately before use, and may be given intravenously or intramuscularly. If the intravenous injection is too rapid, flushing and a fall in blood pressure may occur. Aged solutions of stilbamidine have produced liver and kidney damage, but in a careful study of the toxicity of fresh stilbamidine, Arai and Snapper<sup>197</sup> were unable to show any untoward effects in the liver, kidneys and peripheral blood.

The unpleasant side action of stilbamidine therapy is the development of a facial neuropathy due to toxic degeneration of the principal sensory nucleus of the trigeminal nerve, usually appearing two to five months after treatment. It is characterized clinically by numbness, formication and itching, and a dissociation anesthesia evidenced by a loss of sensation to light touch. Ten out of 18 patients in the series of Arai and Snapper<sup>197</sup> developed this syndrome. The symptoms slowly subside, but the dissociated anesthesia may persist. Continuation of stilbamidine therapy does not seem to aggravate the symptoms.

The recommended dosage is a first injection of 50 mg, a second of 100 mg and 150 mg per dose thereafter. The injections are usually given every other day, but daily doses may be used. In most cases a total of 4 to 6 gm of stilbamidine has been given over a period of four or five months. Snapper<sup>191</sup> considers it essential that the patient be kept on a diet low in animal protein to obtain a therapeutic effect.

The effect of stilbamidine therapy in multiple myeloma is chiefly limited to the relief of severe bone pain. This relief is reported to be so striking that a bedridden patient may begin to walk again after four injections, and it is suggested that ambu-

lation be started cautiously since excessive activity may precipitate spontaneous fractures.<sup>191</sup> The bone pain may be alleviated indefinitely by therapy, and improvement has lasted for a year and longer.

Gibson and Pogge<sup>198</sup> have analyzed the results of a pooled survey of 186 cases of multiple myeloma treated with stilbamidine. Twenty-four and seven-tenths per cent experienced complete relief of pain, the predominating symptom, and 38.7 per cent obtained partial relief of pain. The remainder of the patients were either unaffected or made worse. In 76 of 99 cases studied by serial x-ray examination, there was no increase in the size of the lesions, although regressions were rare. Toxic effects on the blood or kidneys were not reported, but facial neuropathy has, thus far, developed in 30 patients. Stilbamidine had no influence on the course of lymphatic and myeloid leukemia, lymphosarcoma, Hodgkin's disease and carcinoma.<sup>190</sup>

The clinical data indicate that stilbamidine may be of value in the treatment of the severe and often disabling bone pain of multiple myeloma, but there is no satisfactory evidence that it allays the systemic effects, inhibits the extension or prolongs the course of the disease.

Rubenstein,<sup>199</sup> on a rationale similar to Snapper's, recently reported that an antimony-containing compound, neostibosan, produced relief of bone pain and basophilic granulations in the myeloma cells in multiple myeloma. He states that, "in general, our observations on antimony are strikingly similar to those of Snapper, using stilbamidine, a drug containing no antimony."

### *Enzyme Poisons*

Many enzyme poisons have been tested in an attempt to inhibit tumor growth. Since tumor cells are deficient in catalase, Boyland<sup>170</sup> tested a catalase inhibitor, *o*-nitroso-*B*-naphthol. This compound inhibited the growth of mouse tumors at tolerated doses. Brunschwig et al<sup>200</sup> found that sulfhydryl inhibitors, iodoacetate and maleate caused a retardation in tumor growth. Woodhouse<sup>201</sup> obtained tumor inhibition with malonic acid but not with succinic acid. Sodium fluoride, iodoacetic acid, malonic acid and sodium azide have been used clinically in the treatment of leukemia, lymphosarcoma and several types of carcinoma.<sup>202, 203</sup> Alterations in the neoplastic cells and temporary clinical remissions in acute leukemia have been attributed to treatment with one or more of these chemicals.

Kline et al<sup>204, 205</sup> have tested a number of pure chemicals and plant hormones *in vitro* and *in vivo*. The plant hormones had some inhibiting effects on the tumor cells *in vitro*, but were ineffective in inhibiting the growth of tumors in mice and rats. Belkin<sup>206</sup> found di-(hydroxymethyl) peroxide to be without effect in spontaneous transplanted and carcinogen-induced mouse tumors. Suramin (Ger-

manin), an anticoagulant, inhibited the growth of lymphosarcoma in mice, and caused lymphocytic fragmentation.<sup>207</sup> Chambers et al<sup>208</sup> demonstrated that tetraethyl and tetra methyl-o-phenylenediamine selectively damage neoplastic lymphocytes in tissue culture. Thiouracil<sup>209, 210</sup> was of no value in the treatment of leukemia. The injection of one of a variety of amino acids subcutaneously,<sup>211</sup> glycogen intravenously<sup>212</sup> or ethyl alcohol intraperitoneally<sup>213</sup> induced regressions in transplanted tumors in mice or rats.

Geshickter and Reid<sup>213</sup> have made oil-soluble organometallic compounds containing copper, cobalt, manganese, zinc, nickel and iron. Some of these compounds occasionally induced partial and temporary remissions in chronic and acute leukemia, and nickel monobutyl phthalate is reported to produce occasional favorable effects in some cases of carcinoma.

### CASE 34331

#### PRESENTATION OF CASE

A twenty-five-year-old man entered the hospital because of blurring of vision.

During the year before admission the patient was occasionally bothered by shortness of breath on exertion, and three months before admission he noted the onset of moderately severe frontal headaches. One month before admission blurring of vision appeared, which rapidly progressed until it was unsafe for the patient to walk on the street. One week later the headaches became more severe, and periorbital edema was noted in the mornings. There were no episodes of fainting and no epistaxis or symptoms of cerebrovascular accident, no chills, fever, orthopnea, edema of the ankles or increased abdominal girth and no known urinary disease or symptoms.

At the age of six the patient had had an attack of polyarthritis for which he was hospitalized and following which a diagnosis of rheumatic heart disease was made. He was kept out of competitive sports until the age of sixteen, but during the succeeding years he played baseball and filled a job requiring considerable physical effort with no difficulty. Five years before admission he was turned down by the Army because his blood pressure was "a little high."

Physical examination showed the patient to be pale and chronically ill. The eyes showed bilateral congenital zonular cataracts, which somewhat obscured the view of the fundi, nevertheless, numerous flame-shaped hemorrhages, many exudates and a Grade I papilledema were seen. The neck veins were dilated and pulsating. The lungs were clear except for some fluid at both bases. The heart was enlarged, the border of cardiac dullness extending to the left, the sounds were loud and snapping, and there was a widely transmitted Grade III apical systolic murmur. The liver edge was nontender and was felt one fingerbreadth below the costal margin. Shifting dullness and a questionable fluid wave were made out. There was minimal pitting edema of the ankles and sacrum. Chvostek and Trousseau signs were both present.

The temperature, pulse and respirations were within normal limits. The blood pressure was 210 systolic, 135 diastolic.

The hemoglobin was 8 gm, and the white-cell count 13,000. Urinalysis showed a specific gravity of 1.008 and a +++ test for albumin, the sediment contained 10 to 20 red cells, 5 to 10 white cells per high-power field and many granular casts. The nonprotein nitrogen was 90 mg per 100 cc, the total protein 4.48 gm per 100 cc, with an albumin-globulin ratio of 1:41, the serum calcium 5.8 mg and the phosphorus 9.7 mg per 100 cc, and the phosphatase 2.9 units. The sodium was 136.9, the chloride 98, the carbon dioxide 19, and the potassium 7.7 milliequiv per liter.

The patient's output of urine was very poor. He was given a small amount of 5 per cent dextrose in water intravenously and shortly thereafter suffered an attack of acute pulmonary edema. This was treated with morphine, cedilanid and tourniquets. He improved somewhat but then gradually lapsed into coma, developed numerous petechiae and died on the third hospital day.

#### DIFFERENTIAL DIAGNOSIS

DR BERNARD M JACOBSON: To summarize this patient's clinical course, we have the onset of probable rheumatic fever, with rheumatic heart disease many years before admission. Five years before admission he first learned that he had hypertension. About one year before admission he began to suffer dyspnea on exertion, in other words, the first indication of some complication of hypertension. For three months the symptoms consisted mainly of hypertensive encephalopathy and retinitis. We are dealing, then, with a young man who carried a hypertension for at least five years but who began to suffer from probable congestive heart failure one year prior to death.

We are told in the physical examination that the neck veins were dilated and pulsating. Physical signs of that sort make us think of right-sided heart failure or pericardial effusion or constrictive pericarditis. We think especially of tricuspid stenosis. Apparently no x-ray films of his chest were taken during the hospital stay. Is that right?

DR JOSEPH C AUB: Yes.

DR JACOBSON: We would be interested to see the configuration of the heart. We know that we can miss abnormal configurations by physical examination. The lungs were clear. I rather interpret the loud snapping first sound at the apex as probably due to hypertension and hypertensive heart disease. On the other hand, with the widely transmitted Grade III apical systolic murmur, one wonders if he had a diastolic blow. I am sure that we all can miss atypical diastolic blows, especially in a person who already has evidence of heart failure. We would also like to know whether the second aortic sound was louder than the pulmonic or vice versa.

We have evidence later of ascites. The Chvostek and Trousseau signs were undoubtedly due to hypocalcemia. The hemoglobin of 8 gm is not accompanied by a description of the stained smear, but I presume the red cells were fairly normocytic and normochromic, in other words, this was an anemia of the simple, chronic type seen in renal disease. From the study of the urine we get no specific diagnostic information. The picture of renal malfunction gives evidence of both diffuse glomerular and tubular irritation. The patient undoubtedly had been in renal failure for some time because of the nonprotein nitrogen of 90 mg per 100 cc by the time he came to the hospital. The total protein was rather low, 4.5 gm per 100 cc, and does not show the albumin-globulin reversal that we see in such conditions as subacute glomerulonephritis. There was no edema, and one wonders about the accuracy of the figure of 4.5 gm per 100 cc. There was a rather marked hypocalcemia — 5.8 mg per 100 cc, on the other hand, in view of the remainder of the picture, I doubt that we have to worry about primary hypoparathyroidism. This is a picture of hypocalcemia with secondary clinical evidence of tetany that we see every so often in terminal renal insufficiency, regardless of cause. The serum sodium and chloride were within normal limits. The potassium was high, undoubtedly due to renal retention. The carbon dioxide combining power compared with the normal of 25 milliequiv per liter was not markedly reduced. Most people in uremia at this stage of the game should have a more marked acidosis. The terminal episode of pulmonary edema following the intravenous infusion of dextrose and water is a common phenomenon in people with either congestive heart failure or severe renal insufficiency or both.

The presence of petechiae terminally is a common finding in renal insufficiency and denotes some type of vascular purpura. There is no question that the patient died of a combination of congestive heart failure — as evidenced by the symptoms and the distribution of the edema — and renal insufficiency or uremia.

What was the cause of the congestive heart failure? We know that this patient had hypertension long enough to produce hypertensive heart disease. At autopsy there may or may not have been evidence of myocardial infarction or myocardial fibrosis due to coronary-artery disease. What evidence have we that he had any other type of heart disease, such as rheumatic heart disease? I think it is of importance that he was told at the age of sixteen that he had rheumatic heart disease. He undoubtedly was known to have a murmur at that time. I think we have to say that he did have rheumatic heart disease, in addition to the hypertension. I do not believe there is any particular association in this case between the two conditions. Did he have mitral regurgitation, or did he have mitral

stenosis? A good deal of the murmur may have been due to congestive heart failure, part of it, at any rate, to old rheumatic heart disease, and part to hypertensive heart disease. I am a little surprised at not hearing anything about a gallop. Certainly in this terminal stage the patient should have had a gallop, and I would not be surprised if told that he had a pericardial friction rub during the last few days of life.

Certainly the two commonest types of renal lesions we have to consider are either chronic vascular nephritis or malignant hypertension and chronic glomerulonephritis with terminal renal insufficiency. I really do not see any certain way of differentiating these two conditions. Against glomerulonephritis is the fact that we have no history of acute glomerulonephritis or of subacute glomerulonephritis with edema. We have some evidence that the hypertension antedated any knowledge on his part of the urinary abnormalities, and from the level of the blood pressure recorded at entry in the presence of congestive heart failure, one wonders if he had not been carrying a much higher blood pressure during the previous year. This degree of hypertension would certainly be consistent with terminal vascular nephritis. There is nothing in the urinary picture that differentiates the two conditions.

With more renal studies, what other conditions might we encounter? We know that in our diagnoses we must mention chronic pyelonephritis. We have in this case no history of acute infection in the kidneys or a history of renal calculi. There is nothing in the urinary sediment at present that attracts our attention to chronic pyelonephritis. We have a definite statement of fever in the past history but no fever at the time of entry to the hospital. I think we have to discount the possibility of chronic pyelonephritis.

Could this have been an end result of congenital polycystic kidneys? Yes, they may first manifest their presence by the development of hypertension but are certainly far less frequent than malignant hypertension or glomerulonephritis.

Could this renal picture have been due to emboli from the valves of subacute bacterial endocarditis? It could be, but there is no evidence for it. There is no history of fever over a period of time before he came to the hospital and no elevated temperature on admission. There is no statement about any of the other symptoms or ordinary physical signs of subacute bacterial endocarditis. On the other hand, we will not be surprised if Dr. Mallory tells us that the patient had a terminal acute endocarditis.

Could this possibly have been a renal complication of lupus erythematosus? There is no evidence in the past to suggest lupus erythematosus, such as skin lesions, joint symptoms and leukopenia. Could this have been periarteritis nodosa? Again, the absence of fever in the history and the

presence of palpable arterial nodules and eosinophilia at the time of entry make me believe that there is nothing to substantiate that diagnosis. It is merely interesting to mention in passing.

I am going to conclude with a diagnosis of rheumatic heart disease, mitral regurgitation, congestive heart failure, malignant hypertension, chronic vascular nephritis and uremia.

A PHYSICIAN: May I ask whether the phosphatase determination was acid or alkaline?

DR JACOBSON: Undoubtedly it was alkaline phosphatase. The normal value for alkaline phosphatase is 2 to 5 Bodansky units. I suppose it is routine to ask for serum calcium, phosphorus and phosphatase in patients with renal failure. Is that not so, Dr. Aub?

DR AUB: Yes, I might say that I have never seen such a marked Chvostek sign in a uremic patient. He did not have such a very marked drop in calcium when allowance is made for the low plasma protein. Yet it was one of the most marked Chvostek signs that I have ever seen. I do not believe that it could have been due to low blood calcium but to the mechanical irritability that comes with uremia. There was one other sign not mentioned—when the patient was lying down the left upper lobe was full of rales and very congested, when he sat up they all vanished.

DR TRACY B. MALLORY: Is there any comment on the acute pulmonary edema following intravenous therapy with glucose?

DR AUB: In my note I said that it was dangerous to give it, but the only chance of survival was to make him urinate. I also recommended fluid, knowing that he might get pulmonary edema and thinking it was worth the risk.

A PHYSICIAN: How much fluid was given?

DR AUB: Not an enormous amount. He was given 1500 cc of 5 per cent dextrose in water.

DR JACOBSON: It may not be amiss at this point to comment to the effect that I had considered the possibility of lower-nephron nephrosis, such as sulfonamide sensitivity, but in view of the complete absence of such a history I did not discuss it.

A PHYSICIAN: In the face of congestion is it good therapy to give a man of that age intravenous fluids?

DR AUB: I thought it was. It was the only thing we could do for him.

A PHYSICIAN: Would you not use a more concentrated solution instead of so much water if you were trying to bring about diuresis?

DR AUB: You can have your choice. The patient was going to die anyhow.

#### CLINICAL DIAGNOSIS

Subacute glomerulonephritis?

Malignant vascular nephritis?

#### DR JACOBSON'S DIAGNOSES

Rheumatic heart disease  
Mitral regurgitation  
Congestive heart failure  
Malignant hypertension  
Chronic vascular nephritis  
Uremia

#### ANATOMICAL DIAGNOSES

Subacute glomerulonephritis  
Cardiac hypertrophy and dilatation, hypertensive type  
Pulmonary edema, severe  
Bronchopneumonia, slight  
Hydrothorax bilateral, slight

#### PATHOLOGICAL DISCUSSION

DR MALLORY: I think the autopsy showed conclusively that the patient was going to die, as Dr. Aub has said. I rather expected to find very contracted kidneys after reading through the record. At autopsy we found the kidneys to be larger than normal, weighing 450 gm (he was not a large man). They were very pale gray, with yellowish mottling, and the gross diagnosis was subacute glomerulonephritis, that was borne out by the microscopical examination. The other findings at autopsy were a very severe grade of pulmonary edema. The lungs weighed a little over 2000 gm, were very distended and failed to collapse when the thoracic cavity was opened. There was very little pleural fluid—150 cc on each side. Microscopically we found evidence of incipient pneumonia, but the major portions of the lung showed edema rather than infection. The heart did show recognized scars of previous rheumatic infection. The posterior leaflet of the mitral valve was distinctly shrunken, and the circumference of the valve was only 8.5 mm whereas the normal is considered 10 to 10.5 mm. There was a slight degree of mitral stenosis and a more significant degree of mitral regurgitation. The heart weighed 450 gm and the hypertrophy was about equally distributed on the right and left sides, so that I think the hypertrophy was secondary to hypertension as well as to the rheumatic valvulitis. The parathyroid glands were dissected and were not enlarged. Microscopically however, the fat, which is normally present within the parathyroid gland, had disappeared entirely indicating slight hyperplasia.

DR JACOBSON: Do you think that this was subacute bacterial endocarditis arising independently of the antecedent hypertension?

DR MALLORY: No, I think that the hypertension was probably due to the glomerulonephritis. I would have to admit that this was a slow and silent progression of glomerulonephritis, but one sees cases of this type on occasion.

DR JACOBSON: Was there any pericardial effusion?

DR MALLORY No, we found petechiae on many of the serous surfaces similar to those noted in the skin but no pericarditis, and there was no gastritis or colitis as there frequently is in the uremic state.

DR AUB Is there any reason for the bizarre clinical findings in the lungs?

DR MALLORY No, I think the immediate mechanism of death was probably pulmonary edema. The intravenous fluid had been given a full two days before death, however, and the pulmonary edema temporarily cleared, only to recur.

## CASE 34332

### PRESENTATION OF CASE

A sixty-eight-year-old woman entered the hospital complaining of easy fatigability.

About two months prior to admission the patient began to experience progressive weakness and easy fatigability. During this time she had been seen by two physicians, who had been unable to help her. A few hours before admission she developed a severe, steady pain in the right upper quadrant, not affected by breathing or by change in position, and lasting only a few hours. She had not noticed any jaundice, itching or changes in the urine or stools, and had not known of any weight loss.

At the age of thirty-eight she had undergone an apparently normal menopause.

Physical examination revealed a tired, weak, slightly jaundiced woman. A Grade II pulmonary diastolic murmur was heard. A tender, smooth, firm mass was palpated in the left upper quadrant. The edge was not well defined. The mass did not move with respiration and seemed to be medial to the spleen. There was slight erosion of the anterior lip of the cervix.

The temperature was 99.5°F, the pulse 105, and the respirations 24. The blood pressure was 125 systolic, 65 diastolic.

Examination of the blood revealed a red-cell count of 4,200,000, with 15 gm of hemoglobin, and a white-cell count of 11,700, with 79 per cent neutrophils, 13 per cent lymphocytes and 8 per cent monocytes. Examination of the urine showed a specific gravity of 1.020, a +++ test for albumin, acetone and bile, and a green color with a precipitate on sugar test. The serum nonprotein nitrogen was 41 mg, the total protein 5.9 gm, the cholesterol 610 mg and the cholesterol esters 125 mg per 100 cc. The fasting blood sugar was 100 mg, and the alkaline phosphatase 41.8 mg per 100 cc. A van den Bergh test was 6.4 mg per 100 cc direct and 8.2 mg total. The prothrombin time was 18 seconds (control, 19 seconds). The cephalin-flocculation test was + in twenty-four and forty-eight hours. A catheterized specimen

of urine revealed rare colon bacilli and a few non-hemolytic streptococci.

An x-ray film of the chest disclosed no abnormality of the bony thorax. There was some calcification in the right and left first interspaces. The right leaf of the diaphragm was quite high, obscuring the right lower-lung field. There were some linear areas of increased density. The left lung field was not remarkable. The heart appeared enlarged in the region of the left ventricle. A barium enema, with the patient unsatisfactorily prepared, showed no evidence of gross obstruction or gross filling defect in the large colon. A gastrointestinal series showed no esophageal varices. The stomach was displaced to the left and posteriorly by a greatly enlarged liver. No other masses could be made out though there was bulging in the left flank, possibly due to a mass other than the liver. There was flattening along the superior aspect of the proximal duodenum. On the second hospital day a biopsy of the cervix and a vaginal smear were done and both were reported negative.

On the eighth hospital day an operation was performed.

### DIFFERENTIAL DIAGNOSIS

DR JAMES H. TOWNSEND I would be interested to know whether the pain in the right upper quadrant lasted four hours, twelve hours or twenty-four hours. I take it it was the development of this pain, which she had not had before, that brought about the emergency situation that necessitated the patient's entry into the hospital. I should like to know whether the pain lasted for just a few hours before she came into the hospital, and then disappeared before she was seen, or whether, when she came in, the pain required morphine to relieve it. We are not given any information about that as yet. She had not noticed any jaundice, itching or changes in the urine or stools, and she had not known of any weight loss.

At physical examination on admission she was very jaundiced when first seen — I assume only a few hours after the pain developed. I think that is of importance.

The murmur I assume to have been an early diastolic murmur heard in the second left interspace. There was a wide pulse pressure that may have had significance in relation to the murmur.

Examination of the blood was essentially negative, with the white-cell count slightly on the high side, but no anemia.

Let us pause a moment. This patient had bile in the urine. She had acetone, which suggests that she had not been eating well or had been vomiting. She had albumin, which frequently accompanies bile and suggests that perhaps there had been bile there for some time. The green color on Benedict test, which is a frequent finding with

is not necessarily due to sugar, but may be due to some other substance

The cholesterol esters were at about a normal solute level, but the proportion was quite low in relation to the total. The phosphatase was high, and the van den Bergh within middle range. At this point are we told whether there were any cellular elements in the urine — white cells, red cells and so forth?

Presumably the linear areas of increased density described in the x-ray findings were caused by atelectasis associated with the high diaphragm. By x-ray interpretation the liver was greatly enlarged. We are not told on physical examination what the liver edge could be felt in the usual place. May we see the x-ray films at this point?

DR JOSEPH HANELIN: The chest film shows the elevated right leaf of the diaphragm, with a slight amount of linear streaking above it, probably representing atelectasis. The heart is probably enlarged somewhat although it is difficult to be certain of the exact size because the elevated diaphragm may increase the transverse diameter. The lungs otherwise are clear. This film includes the major portion of the abdomen and the barium-filled stomach, which is displaced to the left, presumably by the enlarged liver.

DR TOWNSEND: Can you see the lower border of the liver?

DR HANELIN: I would assume that it was opposite the third lumbar vertebra.

DR TOWNSEND: It is covered by gas so that you cannot define the lower edge too well as to position or exact shape.

DR HANELIN: That is right. We do not see the lower contour. The stomach is displaced somewhat to the left, and in the lateral projection the stomach is displaced posteriorly.

DR TOWNSEND: In the lateral view can you see where the liver is?

DR HANELIN: I cannot definitely outline it.

DR TOWNSEND: The liver is not sufficiently enlarged to push the hepatic flexure into the pelvis, is it?

DR HANELIN: No.

DR TOWNSEND: Most of the liver is above the iliac crest?

DR HANELIN: Yes.

DR TOWNSEND: There are one or two simple laboratory observations that we are not given. I wonder if they were done. We are given a good many blood chemical findings, but we are not told anything about the character of the stools, either the gross appearance or chemical reactions.

DR TRACY B. MALLORY: The stools were brown and guaiac negative. The urine contained a few pus cells, but the number was not estimated.

DR TOWNSEND: But no chemical test was done on the stool for bile pigment or urobilinogen? Was

there a test for urobilinogen in the urine? Evidently not.

We have, then, an elderly woman, with a two months' history of failing health, who had pain only a few hours before admission and at the time of admission was already clinically jaundiced. I am curious to know on which day the van den Bergh test was done, was that observation almost immediately after she came in or after the passage of some days?

DR MALLORY: The test was made on the day after entry.

DR TOWNSEND: She had a reasonably high van den Bergh reaction, which I do not believe developed in the twenty-four hours since she began to have pain. In other words, I believe she had jaundice before she had pain, and this has a different significance from jaundice appearing some days after pain.

The important features of the physical examination are jaundice, an abdominal mass and a diastolic murmur. The blood showed no anemia. We have many of the usual battery of tests done in an attempt to establish the cause of jaundice. In general, we divide these tests into those that point toward obstruction of the extrahepatic biliary passage and those that point toward disturbance of intrahepatic cellular function. Rarely do we get a clear-cut picture. The findings are usually mixed. In this case the high alkaline phosphatase and the high total cholesterol are strongly in favor of external obstruction (probably complete obstruction at these levels), although we would like very much to know whether there was complete obstruction demonstrated by the absence of bile pigment in the stools and the absence of urobilinogen in the urine. However, we do not have that information. The van den Bergh reaction is consistent with complete external obstruction. The slightly low total protein, on the other hand, the relatively low cholesterol esters and the + cephalin-flocculation test point toward damaged liver parenchyma. It was not damaged enough, however, to influence the prothrombin time, which in this case was normal.

The patient was operated on. We have to estimate what was most likely to be found at that operation. Let us look at it from the point of view of the mass described in the left upper quadrant. It was smooth, ill defined and tender. What masses of this sort occur in the left upper quadrant? The kidney is in that region. We have little information about the kidney. At least, there was no blood or pus coming from it. I assume that no intravenous pyelogram was done, or we would have been given that information. On the x-ray films I do not believe that we can see the kidney, and it was not described in the physical examination as a kidney mass would have been. Before examination at the hospital it was thought that it was definitely

not the spleen, and I do not believe that it was the spleen. Could it have been part of the larger mass that the roentgenologists thought might be liver? Yes, the left lobe of the liver might present such a mass, particularly if it was involved with metastatic disease, and that is a definite possibility.

What else could this mass have been? It could obviously have arisen in the pancreas, which is in that region, and pancreatic masses either solid or cystic type, benign or malignant, can present such a mass. They are usually not described as tender. However, I am sure I have seen cases of carcinoma of the pancreas that developed a large, tender mass before the patient died.

If this mass represented a metastasis in the left lobe of the liver, would it have been tender? Usually metastatic masses are not tender, and they are usually not painful. I think it is possible for such a mass to become tender if it is infarcted or has had a hemorrhage in it. I still think that this could have been the left lobe of the liver and that it could have been tender.

Our tests do not give us absolute proof as to whether we are dealing with a straight case of external obstruction or with damage to the liver parenchyma. They suggest a combination. I think that we have to look at the picture as a whole and consider the most probable diagnosis. I gather from the x-ray films that the liver was not tremendously large.

One can say almost with certainty that a liver of this size in a person of this age comes from metastatic carcinoma. The only other condition that frequently causes these very large livers at this age is leukemia, and that I think is ruled out by the blood picture. What was the probable source? We can pretty well rule out the colon. The patient had a pelvic examination, and although not specifically mentioned, I assume that no masses were felt. Probably these metastases did not arise from the pelvic organs, although that is a common source. A small tumor in the ovary can lead to tremendous metastases in the liver. It was apparently not in the stomach. I think it would have been seen if it had been in the stomach, although we all know that a tiny carcinoma in some part of the stomach may not be seen on x-ray study. But I think it is a very distant possibility when painless jaundice comes on at this age. I speak of this as painless jaundice because she was already jaundiced when she was first seen, and there was

not time to develop that degree of jaundice after the pain began. The tumor that causes such a situation usually originates either in the pancreas or in the bile duct. I do not believe that it is possible clinically to differentiate the two. Such liver cancer can also come from metastases from a lung tumor, but from what we can see of the lungs there appears to be no primary source in the nature of a bronchiogenic carcinoma. It is not necessary that the original tumor should have blocked the bile duct. Sometimes metastases themselves, in lymph nodes in the region of the bile duct, can cause such obstruction. I am assuming it was complete obstruction because of the finding of a very high alkaline phosphatase and high total cholesterol. However, the observation of brown stools suggests that it was not complete obstruction, that is a single finding and we cannot rely on it without more chemical tests.

Could this woman possibly have had the one condition that leads to external obstruction and that is amenable to surgery — a stone in the common duct? The possibility is very remote because she had been going downhill and feeling generally well for two months before the onset of pain and because she was jaundiced when first seen within a few hours after the onset of pain.

I shall, therefore, conclude by saying that the probability is that this woman had metastatic disease, presumably carcinoma, in the liver, probably arising from the pancreas, possibly the bile duct, and also possibly from some other source that I have mentioned. I do not believe that cirrhosis of the liver could produce such a picture. One almost never sees such a high cholesterol in cirrhosis of the liver. One can get pain like this in cirrhosis. Can it be a primary tumor in the liver? These are rare tumors usually arising in persons who already have had cirrhosis, of which we have no evidence here, whereas there is considerable evidence that she did not have cirrhosis. She had no esophageal varices. She did have a very high total cholesterol and no change in the prothrombin time. I therefore expect that whatever operation was done — whether it was an exploration, a punch biopsy or a peritoneoscopy — showed metastatic disease in the liver. As a probable source I should think that the pancreas was most likely. The painful mass may have been either the left lobe of the liver or the pancreas.

DR PERRY CULVER I saw this woman with the 4-year students. We were impressed with the severity of the patient's illness, and we were primarily concerned with the epigastric mass. We did not feel the liver at this examination, but in

Out-Patient Department the mass seemed to represent cancer of some sort. We thought it was probably metastatic neoplasm. We admitted the patient to the house immediately as emergency. That is as far as we went with the diagnosis at that time.

I should also like to say that we usually disregard a + cephalin-flocculation test as being within normal limits.

DR TOWNSEND I agree.

DR CULVER Another interesting point is that there is an occasional rare case with brown stools that, on repeated examinations, are completely devoid of bile pigment. Schiff\* has reported this same observation.

#### CLINICAL DIAGNOSES

Metastatic carcinoma of liver

Uremia

#### DR TOWNSEND'S DIAGNOSIS

Metastatic carcinoma of liver (probable primary source in pancreas or bile duct)

#### ANATOMICAL DIAGNOSES

*Carcinoma of gall bladder, with massive involvement of liver and metastases to adrenal glands*

Pulmonary congestion and edema

Cholelithiasis

Pulmonary tuberculosis, old

#### PATHOLOGICAL DISCUSSION

DR MALLORY The operation mentioned was a peritoneoscopy. There had been considerable discussion as to whether or not exploratory laparotomy or peritoneoscopy should be performed. Oddly enough it was the surgeons who did not wish to explore the patient and urged the peritoneoscopy. The liver was studded with tumor nodules. The

patient went rapidly downhill and died without any symptoms of note. At autopsy we found that almost all the liver tissue had been replaced by tumor. In cross-section the largest mass of this tumor was centered around the gall-bladder area, and in the gall bladder was a small papillary tumor, which we believed to be the primary site, with direct lymphatic spread throughout the liver substance. There were very few metastases in the body—two small ones in each adrenal gland and one small metastasis in the bone marrow, found more or less by accident in our microscopical sections. There were no metastases to the lung. The gall bladder contained numerous stones, and we also found three small stones in the common duct which however, was not dilated.

DR TOWNSEND I meant to say that sometimes patients have both carcinoma and gallstones and that perhaps the pain at the time she came in was due to gallstones but I did not believe that stones caused the whole picture.

DR MALLORY Cancer of the gall bladder almost never occurs in the absence of cholelithiasis.

DR TOWNSEND Was the large mass felt on the left side caused by metastases in the left lobe of the liver?

DR ROY V. BUTTLES I could not be sure that the mass felt on the left side was the lobe of the liver. It did not seem to be particularly enlarged.

DR TOWNSEND There was nothing else external to the liver or behind the liver?

DR MALLORY No.

DR JAMES HEIL May I ask about the pulmonary diastolic murmur?

DR TOWNSEND I meant to comment on that also. She may have had old rheumatic heart disease. I assume that a blood Hinton test was done, but I doubt very much the likelihood of a syphilitic process. She may have had sclerotic changes in the aortic valve, which could produce such a murmur in a patient of this age—probably calcific aortic valve disease, not marked.

DR MALLORY We did not find anything to explain the murmur. The heart was entirely normal.

## MEDICAL EXPERTS ON THE ATOMIC AGE

THE world terror characterizing the dawn of the Atomic Age seems at first glance to be something new and unique in human affairs. In a mood of incredulous despair the thoughtful people of the western world stand appalled at the magnitude of the danger. In quite a different mood, scientific experts are now beginning to preach a hard-headed gospel of preparedness. If our courage falters at the earnestness of their words it may be well for us to draw strength from a backward glance to another time when civilization found itself also in an evil case.

It was in the spring of 1242, eighteen years after the mysterious Mongol horde of Genghis Khan had irrupted into eastern Europe to massacre a Christian

army at the Kalka river, thirteen years after the dreaded horse archers had turned back to lay waste northern China while Europe shuddered through an uneasy lull, and three years after the Asiatic terror had again loomed across the Russian steppes.

These last three years had seen eastern Europe suffer the most fearful disasters—far worse than anything Attila and his Huns had brought. "The Mongols," according to Oman\* "represented not mere conquest but blind and wilful destruction, they left deserts behind them where there had been a civilized and thickly peopled group of states and killed for killing's sake." The armored chivalry of Christendom—the best that Europe could produce—melted before them. Nations in their path for got their local quarrels and united, but too late. Now led by Batu Khan, the horde trampled down Russia, Poland and Silesia. On April 5, 1241, they had annihilated an allied army of Germans, Moravians and Poles at Liegnitz and then had rapidly overrun the Balkan peninsula. Now indeed "a shock of terror went round the whole of Christendom." The last barrier was down, and with the approach of spring Batu Khan stood at the unprotected German border. Doubtless the unheeded warning of the River Kalka and the far-off fate of China were then remembered, and the thirteen wasted years of the "cold war" regretted. Western Europe saw its "atomic age" close at hand, and it was appalled.

But then, as now, there were experts to substitute reasoned action for despair. Observing siegecraft to be the weak side of Mongol tactics, military engineers advised building strong fortresses and castles—the people built them. Advised to unite for common defense, the nations united and braced themselves for inevitable disaster, but disaster never came. Batu Khan, after breaking his teeth on the first strongly fortified and defended cities suddenly faded into the east, and Western Europe, after a year of intense terror, finding itself inexplicably freed from all danger, was able to resume its endless local wars.

On August 6, 1945, a detonation over Hiroshima announced the advent of our own Atomic Age. Again the shock of terror, which is not new, is

\*Oman, C. *A History of the Art of War in the Middle Ages*. Second edition. 2 vol. London: Constable & Co. 1924.

ing felt round the world. And again the experts speaking.

Colonel Wesley C. Cox and Major A. J. Bauer, Army Medical Corps experts from the Surgeon General's Office, discussed "Military Epidemiology and Preventive Medicine in the Atomic Age" at the Harvard School of Public Health on May 26, 1948. Their remarks dealt with two aspects of the problem of preparedness: the immediate implications of an atomic bomb attack within the next five years, and the broader implications of producing a civilization capable of surviving the consequences of atomic bomb attacks in a more remote future.

They began by pointing out the enormous shocking power of the latest explosives, and the magnitude of the devastation one bomb can cause. Between 15,000 and 200,000 casualties can be expected in a city of 1,000,000 population. All the measures now taken in cases of widespread disaster will be needed, but on a vastly larger scale. Tremendous supplies of drugs, dressings and other medical equipment will be required. Blood transfusions will be used in fantastic numbers. Treatment of initial injuries will involve rescue, evacuation, sorting, nursing care, antibacterials, vitamin C, intravenous administration of fluids and blood and the surgery of trauma and burns. Later treatment of survivors may be directed to the effects of radiation illness, the radiation damage being evaluated by frequent lymphocyte counts. Agents of questionable value such as vitamin B<sub>12</sub>, toluidine blue, protamine sulfate, rutin and adrenocortical hormones may be used. "Of first importance following the rescue and first-aid ministrations to those known to have been exposed to excessive radioactivity is the administration of drugs to prevent the development of capillary and vascular fragility." Many laymen will have to be taught the technique of blood grouping, transfusion, cell counts and other medical skills to supplement the efforts of the physicians. Each community will have to organize a "civil-defense task-team" made up of experts in several fields as well as a civilian-defense force based on the experience of the English in World War II. A grim note is sounded by the statement that "the director of the emergency plan for one city must be a resident in some other community. Shelters, potable water,

waste disposal, food spoilage both by irradiation and by electric power disruption, detection and control of epidemics must also be envisioned. "The power of this weapon is so great that we cannot afford not to plan as long as any possibility of attack is present."

Colonel Cox and Major Bauer then spoke of the long-range plans that may be necessary if humanity is to survive in the Atomic Era.

The advent of the Atomic Period has oriented us to new concepts and wider horizons. We have adopted a broader view of democracy and fully recognize that although we are in a time of technocracy we have also entered into an era of renewed interest in the individual.

This leads them to discuss such apparently diverse subjects as trends in medical education, means of extending the span of economic usefulness in an aging population, the elimination of chronic diseases, eugenics, maternal health, periodic health examinations, prevention of dental caries, child psychology as an approach to reducing later neuropsychiatric instability, dietetics, and many others. "Only through such comprehensive National programs may we envision the development during the future Atomic Era of a physically strong, well-developed population, psychologically and mentally well conditioned and hardened and free of the preventable defects, disabilities and diseases which have so long plagued us."

Major Bauer ended with a thought that must surely have entered the minds of the thirteenth-century military experts while they were pushing their fortifications to completion.

The most important preventive measure in preparation for an atomic bomb attack is outside of our field. That is a national policy which will make all of our efforts superfluous.

## STREPTOMYCIN RESISTANCE OF TUBERCLE BACILLI

It is now well known that the development of resistance of the infecting organism is one of the most important limiting factors and the greatest cause of failures of streptomycin in the treatment of tuberculosis. Two recent studies shed further light on certain aspects of this phenomenon.

## TERATOGENETIC AND LETHAL EFFECTS OF EMBRYONIC INFECTIONS

THE recent observations on the occurrence of congenital defects in the offspring of mothers who have had rubella during pregnancy have stimulated interest in the whole subject of intrauterine or embryonic infections and of all types of infections and illnesses in the mother during pregnancy. An interesting experimental approach to this subject was made by Hamburger and Habel\* For their studies they used infections with influenza A and mumps virus in the developing hen's eggs

The chick embryo suggested itself as a suitable embryonic material since it is known that the tissues of the extraembryonic membranes of the chick embryo are a favorable medium for the culturing of a number of viruses. Furthermore, the absence of a placenta in the developing chick makes a direct infection of the embryo possible, thus avoiding the complications introduced by an extraembryonic barrier

The experimental evidence produced from these studies showed that the influenza A virus has teratogenic effects on the early chick embryo. It produced a specific syndrome comprising microcephaly and micrencephaly, twist of the axis and impairment of the growth of the amnion. Furthermore, the virus was lethal for early embryos within three days of infection. The mumps virus was likewise lethal for early embryos five days after infection, it did not produce specific abnormalities, but seemed to raise the incidence of malformations of the types that occasionally occur in uninfected chick embryos

The authors believe that their results place influenza A virus in a line with the rubella virus as a tera-

togenic agent. Their observations on influenza A infections in chick embryos also confirmed those on rubella in human beings in that only infections of early embryos resulted in abnormalities. Chick embryos of four days incubation were killed by the influenza virus, but it seemed that in that stage of development most organs have passed the critical period at which their morphogenesis could be directed into atypical channels

Their findings were also of interest in that the patterns of infectiousness were different for the embryo and for the fully developed structures. In the embryo the brain tissues seemed to be particularly susceptible to influenza A virus, whereas in the adult the respiratory mucous membranes were primarily affected. In mumps the infection of the salivary glands is not infrequently combined with meningitis, but no effect on the brain was found macroscopically in embryos. Hamburger and Habel regarded the situation with mumps in chick embryos as the same as that in rubella during pregnancy, in which the embryonic defects seem to have no obvious relation to the manifestations of rubella infections in older phases of life

## MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

### REIMBURSEMENT FOR HOSPITAL CARE

Reimbursement for the hospital care of a patient with venereal disease who cannot afford to pay for hospitalization has been increased from \$4.50 to \$6.50 per diem, in accordance with Chapter 669 of the Acts of 1948, the Massachusetts Department of Public Health announces. This increased rate, which became effective on July 1, 1948, shall constitute reimbursement in full for all services rendered the patient

## MISCELLANY

### NEW YORK UNIVERSITY HEALTH-EDUCATION INSTITUTES

A series of annual health-education institutes is to be held at New York University under the sponsorship of the School of Education. The first of these institutes to be held this summer from August 16 to September 3, 1948, under the Department of Physical Education and Health, School of Education in co-operation with the American Association for the Advancement of Science, the Research Council on Problems of Alcohol and other national agencies, will be devoted to problems in alcohol education

\*Hamburger A. and Habel E. Teratogenic and lethal effects of influenza A and mumps viruses on early chick embryos. *Proc Soc Exptl Biol & Med* 66 60-617 1947

Sadusk and Swift<sup>1</sup> tested the *in vitro* streptomycin sensitivity of tubercle bacilli isolated from sputum or gastric washings at monthly intervals in a group of 16 patients with pulmonary tuberculosis receiving 1.8 gm of streptomycin daily for a period of four months. In these cases 14 of the strains of bacilli isolated before treatment were sensitive to 0.5 microgm of streptomycin per cubic centimeter of the culture medium used, and 2 were sensitive to 1.0 microgm. Loss of sensitivity of the organisms, as evidenced by at least tenfold increase in resistance, began to appear by the end of the first month of therapy at a time when conversion of positive sputum or gastric washings to negative was observed in cultures of other cases. By the end of the third and fourth months of therapy 9 patients still had positive cultures, in 5 the organisms had increased tenfold to fiftyfold in resistance, and the remaining strains increased from one hundredfold to more than two thousandfold in resistance. There was no clear-cut correlation between resistance to streptomycin and the clinical course of these patients under therapy.

Another more detailed and somewhat more illuminating study was reported a few months previously by Pyle,<sup>2</sup> who made direct quantitative studies of the sputum of 8 patients with far advanced tuberculosis who were raising large amounts of sputum that was loaded with tubercle bacilli. These people were treated with streptomycin continuously with a dosage of 0.25 gm every six hours for four or five months. In each case the sediment from a twenty-four-hour specimen of sputum was concentrated to determine the total number of organisms present. The specimen was cultured on plates containing graded concentrations of streptomycin, and the number of organisms growing without the streptomycin and in varying concentrations of the agent was determined. This was repeated at weekly intervals throughout the course of treatment.

In 7 of the 8 cases a few relatively resistant organisms were found in the cultures of the sputum obtained before streptomycin was started. In each of these cases from four to forty-two colonies grew on plates of mediums containing 5 microgm, from one to eight colonies grew in 10 microgm of strep-

tomycin per cubic centimeter, and no colonies grew on mediums containing 25 or more microgm per cubic centimeter before treatment was started. The total bacterial count in the same amount of inoculum in 2 cases was in the vicinity of 100,000 and 350,000.

It was evident from these pretreatment studies that any large population of tubercle bacilli could be expected to contain organisms that are relatively resistant to streptomycin without having previously been exposed to the drug. In all 8 cases, however, the predominant strains of *Mycobacterium tuberculosis* were sensitive to from 0.6 to 1.25 microgm.

In 4 of the 8 cases the originally predominantly sensitive strains of tubercle bacilli were replaced during therapy by strains that were predominantly resistant to 1000 or more micrograms of streptomycin per cubic centimeter. In an additional case the strain became sensitive to 50 microgm at the end of eight weeks, in 2 cases the strains retained their original sensitivity throughout, and in the final case only a minimal degree of resistance occurred at the end of four and a half months of treatment.

In the 4 cases in which resistance developed the weekly cultures showed a more or less gradual increase in the number of resistant organisms and in the degree of resistance to streptomycin. This increase began within one to four weeks after treatment was begun, although the strains were not predominantly resistant until from six to thirteen weeks. For example, at the time when a number of colonies grew in medium containing as much as 100 microgm of streptomycin per cubic centimeter the vast majority of the bacterial population was still quite sensitive to streptomycin and the patients presumably could be expected to continue to receive benefit from chemotherapy.

From a practical point of view these findings suggest that most of the benefits that take place from streptomycin treatment in the majority of cases of tuberculosis will be obtained during the first month of treatment, and thereafter the effects of therapy decline so that probably no benefit is obtained after the end of two or three months. This is true, at least in the cases in which a sensitive flora is

iced by a predominantly resistant one during course of treatment

## STATISTICALLY SPEAKING

*To the Editor* I should like to call attention to the following facts in reference to the article, "Swimming Pools: Their relation to illness," by Dr. J. Roswell Gallagher, which appeared in the June 24 issue of the *Journal*.

Upon examination of the statistics presented in Table 1 of the article, one finds that the average number of hospital admissions for swimmers (0.354) is wrong. This average was obtained by adding the hospital admissions per swimmer (0.770 plus 0.290 and so forth) and dividing by 7. This is an unweighted average, since it does not take into account the number of swimmers in each year. The correct, weighted average is obtained by dividing the total number of hospital admissions (of swimmers) by the total number of swimmers. I have calculated these values and found that the total number of admissions (269) divided by the total number of swimmers (815) gives the true average of 0.330 hospital admissions per swimmer. Similarly, the figures for nonswimmers were calculated and the total number of admissions (1068) divided by the total number of swimmers (3500). Curiously enough, this weighted average equals the unweighted average of 0.305.

The percentage increase of admissions of swimmers over nonswimmers is now only 7.5 per cent. Upon closer statistical analysis of this figure it turns out that the standard deviation of the difference of the averages is 0.018. Since the difference of the average (0.330 minus 0.305) is only 0.025, the deviation from zero or 0.025-0/0.018 is 1.4 sigma. This means that the figure 7.5 per cent is statistically not significant. Thus the difference between swimmers and nonswimmers could easily occur by chance alone.

Since reference to Dr. Gallagher's article was made in the current issue of *Time* without Dr. Gallagher's cautious reservations regarding the validity of the figure 14 per cent, and since exact evaluation of the data yields only 7.5 per cent with a deviation of 1.4 sigma, making this figure without statistical significance, I believe that these findings should be brought to the attention of the editors of *Time* so that the lay population may not be misled. The readers of the *New England Journal of Medicine* might also be interested in these findings.

HANS W. NEUBERG '50

College of Physicians and Surgeons  
Columbia University

Mr. Neuberg's letter was referred to Dr. Gallagher whose comment is as follows:

*To the Editor* This is a valid comment. Through an oversight the raw data in Table 1 were not reduced to a "per boy" basis, the method that was used in the other similar tables in this paper. The discussion and summary, however, made it clear that the differences in illness were slight.

J. ROSWELL GALLAGHER, M.D.

## NOTICES

## ANNOUNCEMENT

Dr. Thomas B. Quigley announces the removal of his office to 319 Longwood Avenue, Boston.

## WANTED BY THE FBI

Hugo Bob Hubsch, with aliases of Robert C. Glass, R. C. Harris, Hogo Hobsch and Louis S. Miller, is being sought by the Federal Bureau of Investigation. On November 7, 1945, a Federal Grand Jury at Jackson, Mississippi, returned an indictment charging this man with a violation of the National Stolen Property Act. He is charged with another violation of the National Stolen Property Act in a complaint filed with a United States Commissioner at Birmingham, Alabama, on June 7, 1948. This man has defrauded numerous physicians and hospitals in the Eastern and Southeastern sections of the United States during the past few months through the medium of fraudulent checks.

Investigation has revealed that Hubsch has a chronic kidney ailment, and it has recently been ascertained that he has a large kidney stone in the right ureter about 10 cm. below the kidney. This condition has caused local inflammation, which, at varying intervals, results in almost unbearable pain. He has been advised that it will be necessary for him to undergo major surgery for the removal of the stone in the

near future, and until that surgery is performed he will need frequent, if not continuous medical attention. This fugitive moves about rapidly in the section of the United States east of the Mississippi River, and he has recently given numerous physicians and hospitals fraudulent checks in return for treatment, hospitalization, sedatives and narcotic prescriptions.

The following is a composite description of Hugo Bob Hubsch: age, about fifty-two (claims to have been born in Budapest, Hungary, on November 4, 1895); height, about 5 feet, 6 inches; weight, 140 to 170 pounds; hair, dark brown; graying eyes, brown build, medium; race, white; nationality, believed to be naturalized American; occupations, laborer, pharmacist; scars and marks, left arm partially paralyzed; needle scars on both arms, large scars above each hip resulting from kidney operations, shrapnel scars and two bullet scars on abdomen, bridge in upper front teeth characteristic, long nose, stooped posture.

Anyone having information concerning the whereabouts of this fugitive should immediately notify the nearest office of the Federal Bureau of Investigation or the local law-enforcement agency.

## ANNUAL MEETING OF NATIONAL COMMITTEE FOR MENTAL HYGIENE INC

The annual meeting of the National Committee for Mental Hygiene will be held on November 3 and 4 at the Hotel Pennsylvania, New York City. The program will consist of four scientific sessions during the mornings and afternoons, a business luncheon on the first day and the annual luncheon on the second day at which the presentation of the Lasker Award of \$1000, presented annually for outstanding service in the field of mental hygiene, will be made and the ten-day national program for mental health discussed.

Further information may be obtained from the National Committee for Mental Hygiene, 1790 Broadway, New York 19, New York.

(Notices concluded on page xiii)

## NOTICES (Concluded from page 282)

AMERICAN CANCER SOCIETY  
ANNOUNCEMENT OF GRANTS AND FELLOWSHIPS

The Committee on Growth of the National Research Council, acting for the American Cancer Society is entertaining applications for grants and fellowships. Applications for extension of existing grants in cancer research will be received until October 1, and applications for new grants until November 1. Final decision on applications submitted during this period will be made in most cases soon after February 1. Grants approved at this time ordinarily will become effective July 1, 1949.

Fellowship applications may be submitted at any time. Those received prior to November 1 will be acted upon by the Committee on Growth in December. Those received between November 1 and March 1 will be acted upon in April. Fellowships ordinarily will begin July 1, though this date may be varied at the request of the applicant.

During the past year the American Cancer Society, Inc., on recommendation of the Committee on Growth has approved research grants and fellowships totaling over \$2,000,000.

Communications regarding grants and fellowships should be addressed to Executive Secretary, Committee on Growth, National Research Council, 2101 Constitution Avenue, N.W., Washington 25, D.C.

# BRIEF HISTORICAL NOTES ON MEAD'S CEREAL, PABLUM AND PABENA

---

**H**AND in hand with pediatric progress, the introduction of Mead's Cereal in 1930 marked a new concept in the function of cereals in the child's dietary. For 150 years before that, since the days of "pap" and "panada," there had been no noteworthy improvement in the nutritive quality of cereals for infant feeding. Cereals were fed principally for their carbohydrate content.

The formula of Mead's Cereal was designed to supplement the baby's diet in minerals and vitamins, especially iron and thiamine. How well it has succeeded in these functions may be seen from two examples:

(1) As little as one-sixth ounce of Mead's Cereal\* supplies over 50% of the iron and 20% of the thiamine minimum requirements of the 3-months-old infant. (2) One-half ounce of Mead's Cereal furnishes all of the iron and 60% of the thiamine minimum requirements of the 6-months-old baby.

That the medical profession has recognized the importance of this contribution is indicated by the fact that cereal is now routinely included in the infant's diet as early as the third or fourth month instead of at the sixth to

twelfth month as was the custom only a decade or two ago.

In 1933 Mead Johnson & Company went a step further, improving the Mead's Cereal mixture by a special process of cooking, which rendered it easily tolerated by the infant and at the same time did away with the need for prolonged cereal cooking in the home. The result is Pablum, an original product which offers all of the nutritional qualities of Mead's Cereal, plus the convenience of thorough scientific cooking.

During the last twelve years, these products have been used in a great deal of clinical investigation of various aspects of nutrition, which have been reported in the scientific literature.

Many physicians recognize the pioneer efforts on the part of Mead Johnson & Company by specifying Mead's Cereal and PABLUM—and also the new Pablum-like oatmeal cereal known as PABENA.

---

\*Pablum, the precooked form of Mead's Cereal, has practically the same composition: wheatmeal (farina), oatmeal, cornmeal, wheat embryo, beef bone, brewers yeast, alfalfa leaf, sodium chloride, and <sup>40%</sup> reduced iron.

## THE COUNTRY DOCTOR ON THE MAINE COAST\*

MARY ELLEN CHASE, PH D †

NORTHAMPTON, MASSACHUSETTS

MOST persons in my profession, which is the teaching of English Literature, cherish a devotion to the ancient Greeks of the fifth century B C, that golden age of poetry and drama. I share that devotion. My freshmen at Smith College always read with me a play or two of Euripides or of Sophocles, and I take great pleasure in reading to them the *Apology*, the *Crito* and the *Phaedo* of Plato so that they may know at least something about the life, the noble thoughts, and the death of Socrates.

But there is one Greek writer of this great and golden age of Pericles whom I do not share with my freshmen. He is reserved for my own delight, for those hours when one escapes from students either by going to bed with a book or by driving to the Berkshires in one's car, or by locking oneself within one's office and placing a curt sign upon the door. This ancient writer needs no introduction to this audience. You have been familiar with his name from the day you entered medical school. You are bound by his oath, and you doubtless know far more than I know about those books which he left behind him, some perhaps not written by him but all concerned with ancient medicine and all known by his name. I refer, of course, to Hippocrates, and to his books dealing with acute and chronic diseases, with fractures and head wounds, and swollen joints, with epilepsy, called by him "that sacred disease," with fevers, which seem to have been his chief interest, with childbirth and even with the common cold.

My first interest in Hippocrates began years ago in college when I had two passions: one the study of Greek, the other the dream of being a country doctor and ministering to the sick. The first in my youth was quite safe and sane, the second I kept discreetly to myself, for in those days, at least in rural Maine, the idea of a woman studying medicine was a completely insane notion. Needless to say, the second dream never came true. I must wait for another world for its realization, but the first pleasure—that of the study of Greek—has never

left me, although my early knowledge of that language has become tarnished and wasted with the years. I fortunately, however, possess the *Loeb Classical Library*, which gives me Hippocrates in four volumes, and I often delve into these, since the English translation is happily on each opposite page.

Hippocrates, as you know, came from the Island of Cos in the Aegean Sea. He must, therefore, have been reared among island people, fishermen and sailors, and I have a feeling that rural doctoring must have been interesting to him even after he went to Athens and became the great physician of his age and the teacher of young medical students as well. At all events among his many treatises, case histories and medical aphorisms, he has a good deal to say about the dignity of the profession in general, about the behavior of doctors toward their patients and about certain simple remedies that have always reminded me of the ones I grew up with as a child on the coast of Maine. I have chosen a few of these warnings and prescriptions to use as the framework to what I shall try to say about the country doctor as I knew him on the Maine coast many years ago.

Hippocrates says that doctors should always be clean and well dressed and smell pleasantly. The two country doctors, named, respectively, Dr. Rufus Grindle and Dr. Otis Littlefield, whom I knew for many years in the village of Blue Hill, Maine, and one of whom brought me into the world, were, I am sure, as clean as a Saturday night bath by the kitchen stove could make them. They dressed as well, I am sure, as their slender resources allowed, and they surely smelled strongly and, to me, at least, pleasantly, since they always carried about with them the smell of the barn where they cared for their horses and cows, of the old laprobes, which they sat under all winter on their household calls—in other words, of harnesses, manure, hay and grain bins.

Hippocrates says in several places that nature is the best doctor and that most sick people recover anyway of most ailments simply by the wise provi-

\*Presented in part at the annual meeting of the Massachusetts Medical Society, Boston, May 26, 1948.

†Professor of English Language and Literature, Smith College.

sion of the gods who have made us as we are. We surely believed that doctrine on the Maine Coast in my childhood. We depended on the body to right itself by itself, and the remedies we used to help it along were, for the most part, those of nature herself, gathered from her own fields and pastures. A great-aunt of mine was a faithful herb gatherer, bringing home all summer apronfuls of pennyroyal, wintergreen, wormwood, camomile, thoroughwort and mullein, and, whether we were ill or not, we drank huge quantities of the liquids brewed from these just as a precautionary measure against any diseases that might be lurking about. In addition, our home like most others kept on hand a bottle of Jamaica ginger, one of castor oil, one of Johnson's horse liniment, some spirits of niter, some essence of peppermint, some paregoric, and plenty of homemade cough syrup made by boiling molasses and vinegar together. There were plenty of onions for poultices, and the salt pork barrel in the cellar could always provide a generous slice, which, sprinkled with pepper and bound about a sore throat, was almost certain to cure it.

In fact, when I was a child, to call the doctor in was a momentous family decision. In the first place, it meant that the case was too serious to depend any longer on nature, assisted only by household remedies. In the second place, it meant that you were financially prepared for an unusual expenditure of money. Of course, if you were at all able, you went to the doctor's office at his house, a much confused room in which there was everything under the sun from an old couch, on which you might be asked to stretch yourself, to a checkerboard, upon which, after your professional interview was over, the doctor might ask you to try a game with him. Such an office visit cost you only fifty cents whereas a call at one's home cost a dollar. And in the third place, to call the doctor in meant that you were pleasantly prepared to receive great importance and concern in the eyes of your neighbors. When I was a child, the saying, "She's Had the Doctor," was one to conjure with. A child who had the doctor for anything short of a broken leg or a bad case of measles was raised to indescribable importance among his playmates, and a country woman who had the doctor for anything but the advent of a baby was assumed to be at the door of death.

When the doctor was once summoned, which meant a journey to his house in pre-telephone days or, if you lived far in the country, a message carried by a worried neighbor who was driving to the village, the whole family prepared for him in hushed silence. Clean sheets were put on the bed of the patient, who himself was in a dither of excitement and importance, the house was tidied up, clean towels were placed by the kitchen sink, a kettle of water was kept boiling on the stove, and the best sauce dishes were laid out to receive the doctor's pills and powders. Meanwhile all the unoccupied

members of the family found some excuse to call upon the neighbors to give the ominous word that the doctor had actually been called.

The doctor always took his time in coming. He had, of course, to get his black bag ready, to harness his horse and perhaps to drive several miles over all manner of roads. I remember the untold excitement that prevailed when at last he drove into our yard, hitched his horse to the barn door, or left him standing unhitched, and came through the side door into the kitchen. We all stood about in awed silence. My mother in a clean white apron stood ready to execute his commands and to conduct him to the sickroom. He always rubbed his hands over the kitchen stove if it were winter, then washed them at the kitchen sink, and dried them on the best towel laid out for him. Then he was likely, before he was taken to the patient, to have a word with each of us, to chat pleasantly about the weather or town affairs, and even, in spite of his Hippocratic oath, to gossip a bit about his other patients, who were, of course, known to us.

My mother always accompanied him to the sickroom, carrying a tumbler of fresh water, a towel and a spoon, by which he could look down his patient's throat. The first thing, as I remember it, that the doctor always said, after he had shaken hands cheerfully with the patient and inquired minutely about all his symptoms, was a remark I rarely, if ever, hear today: "Let's see your tongue." After the tell-tale member had been scrutinized, and the pulse and temperature taken, the doctor began thumping and prodding most of one's anatomy, looking for rashes, feeling one's feet.

This done he made a pleasant social visit with his patient, to whom he was careful to say nothing alarming about his condition. He talked of village affairs and coming events, ball games and horse races, or anything else that might be diverting. It was characteristic and, I may say, wise of our country doctors, if the patient happened to be the head of the family, to say nothing of politics. As a matter of fact, although Dr. Rufus Grindle was a staunch Republican, Dr. Otis Littlefield was an equally staunch Democrat in an overwhelmingly Republican community. Most heads of families who employed him deplored his politics, but welcomed his skilful ministrations and admired him in spite of his unfortunate political principles, which he was careful never to bring into a Republican sickroom lest mounting fever should result. Dr. Rufus Grindle was equally careful not to argue on politics with any rare patient who was a Democrat.

When the doctor emerged at last from the sickroom, my mother led him to the parlor, where behind closed doors they conferred together. Both our doctors, and I am sure all others on the Maine coast in those days, had high regard for the common sense, skill and even medical knowledge of country mothers and always treated them with

great respect Neither of our doctors really approved of my mother's homeopathic case, which contained little bottles of pleasant pills marked "Aconite," "Belladonna" and "Nux Vomica," but she used it all the same The doctors did approve however, of various other treatments, in fact, my mother, like many other New England women, was known far and wide for her knowledge of how to treat the sick

For earache she used a large raisin, which she heated on a hatpin over a kerosene lamp and placed in the ear, followed by a bit of cotton This operated, I presume, on the principle of a fireless cooker, and I remember many an earache soothed by it The great Galen, physician to the Roman Emperor, Marcus Aurelius, is said to have prescribed for toothache and swellings of the face tiny frogs boiled until they were steaming hot and like the raisins, capable of retaining heat For chest colds my mother first rubbed us lavishly with hot grease (goose or duck grease, if it were at hand) and then put on a stinging plaster made of mustard and white flour Even Hippocrates, who depended a great deal on sweating, did not regard it more highly than my mother and our country doctors We used to sit for half an hour before bedtime with our feet in a pail of hot mustard water Then we were put to bed surrounded by hot soapstones and in the morning we were damp but cured

Hippocrates has a great deal to say about gruel He believed it should be made of barley meal, either thick for nourishment or thin for sweats Our doctors agreed with him, and so did my mother "Give her some gruel all she wants," our doctors used to say I never hear a doctor use this old word nowadays, nor can I find a recipe for gruel in my modern cookbooks, but it used to be delicious in a yellow bowl and always gave one that pleasant sense of being ill and, therefore, important

When all these prescriptions had been suggested and the doctor had left his medicines, pink pills in one saucer, some neatly folded white powders in another, he prepared to take his departure, although he never seemed to be in the least of a hurry While he was strapping up his black bag, my mother produced his dollar, for most families preferred to pay him on the spot He always stuffed the bill into a pocket as though he were not much concerned with it

My mother and I a few years ago had an amusing time reckoning the doctor's bills of our family of six children over a period of sixteen years, from 1886 to 1902 According to our good memories assisted by some accounts of hers they all amounted to the sum of \$105 This amount had paid for the advent of six babies, six cases of measles, one serious case of rheumatic fever, one very bad cut with an axe six vaccinations for smallpox and a supply of medicine for the sixteen years I came into the world at a cost of \$8 00 — \$5 00 for my birth and

three follow-up visits to my mother at \$1 00 each My brothers and sisters cost the same, which meant an outlay of \$48 to start the Chase family The measles, since we all had them at once, cost \$4 00 for four visits, and the axe injury set us back \$7 00, the vaccinations performed in the doctor's office cost 50 cents each, and the rheumatic fever, which gave us enormous social prestige since the doctor came every day for a month, cost \$31 The rest of the \$105 paid for all the medicine, not of our own making I do not know the cost of a brother and sister born after 1902, but I do not assume that it was much higher I may add that all eight of us flourish today in spite of our humble beginnings and modest cash price!

Hippocrates and the great Galen after him, in ages rife with superstition and quackery, did not like superstitions, and yet they say that sometimes a belief in them proves helpful to the patient either in curing disease or in warding it off Our doctors did not like them either, though they laughingly tolerated them, but yet we flourished on them We wore each year a camphor bag all winter on a string around our necks, in the spring we were fed a tablespoonful of sulfur and molasses according to the mystic formula of three days and skip three, in the summer we were solemnly warned, and as solemnly believed, that the eating of chokecherries followed within three hours by a glass of milk meant certain death, and we just as solemnly believed that a horse chestnut, carried in one's pocket, would ward off rheumatism and any number of other disasters A black cotton stocking, worn for at least a week without washing, was believed to cure a sore throat, if it were bound around one's neck at bedtime with the heel against the Adam's apple I have gone to bed many times with one around mine

Hippocrates says that of all professions that of medicine is the most distinguished since it aims not only to heal the body but also to calm the mind and spirit This truth the country doctors of the Maine coast, and elsewhere of course, understood well They had never heard of psychiatry, but they knew people, their families, their circumstances, and their worries and they seemingly had all the time in the world to "talk things over" with their patients Dr Rufus Grindle often brought books along, which he thought his patients might enjoy, and while his old white horse often got tired of waiting and ambled home without him, he might be playing a game of checkers with someone not long for this world Money never seemed to worry either of our doctors They cheerfully took their pay, if necessary, in potatoes, lobsters, or a day's labor in their gardens or at their woodpiles In terms of affection and understanding as well as of healing, they cared for their patients

Even now along the outhing districts of the long Maine coastline, they are not extinct They go hither and yon in their old Fords, chug out to

lonely islands in motorboats, still know their patients as their friends. One of them told me recently that he was still delivering babies on wide-leaved kitchen tables and that he still sometimes resorted to a feather stuck in the patient's nose to induce helpful sneezings. And Dr. Otis Littlefield, who died six years ago at over eighty, full of years and good works, told me a short time before his death, with pardonable pride, that over a practice of fifty years he had brought nearly 1000 babies into the State of Maine and had never lost one of them—or a mother. Quite a record for a country doctor.

Thus is Maine today not bereft of her country doctors. In a State almost wholly rural, except for four or five considerable cities and towns, the doctors are general practitioners rather than specialists, although we boast of some eminent specialists and surgeons also in our hospitals and our cities. We are proud, too, of our small hospitals as well as of our large ones in Portland, Bangor and Lewiston. In my native village of Blue Hill we have a small but beautifully equipped hospital under the able charge of Dr. Raymond Bliss, who for twenty-five years has had an eminent name as a skillful surgeon as well as a general practitioner. Many of our summer residents on the coast, who have been most generous with financial help in building our hos-

pitals, show their confidence in our Maine village doctors and dentists by coddling along their ailing teeth, their appendixes and their gall bladders until the summer comes and they can have their earthly tabernacles depleted, renovated or refurnished by our country dentists and doctors. Our Maine country doctors still have time for their patients' troubles as well as for their bodily ills, and they are still looked up to and honored by us all.

I should like to say a few words in closing—making myself for the moment as spokesman for our small Coast hospitals and our village doctors—in gratitude for a service given here from 34 Bennet Street under the Bingham Foundation. I am told by Maine doctors that the courses given under this Foundation to doctors and technicians is the greatest single help the doctors in Maine have ever had, services that have inestimably benefited the Maine physicians, laboratory technicians and hospitals, and therefore Maine people at large. For this the doctors and the people of the State of Maine are grateful to the State of Massachusetts—states that, until 1820, were both the State of Massachusetts and, even today, in the character of their people, in their coastlines, and in their country villages and their country doctors, are still one and the same.

## SERUM CONCENTRATIONS OF PENICILLIN FOLLOWING THE ADMINISTRATION OF CRYSTALLINE PROCAINE PENICILLIN G IN OIL\*

WILLIAM L. HEWITT, M.D.,† PHILIP WHITTLESEY, M.D.‡ AND CHESTER S. KEEFER, M.D.§

BOSTON

THE use of peanut oil and beeswax suspensions of amorphous calcium penicillin and of the sodium and potassium salts of crystalline penicillin G for delaying its absorption when injected intramuscularly is well known. The recent preparation of the crystalline procaine salt of penicillin G has afforded the opportunity for studying the absorption of a relatively insoluble salt.<sup>1,2</sup> Procaine penicillin is a true salt derived by the stoichiometric combination of procaine hydrochloride and sodium penicillin G. Calculated on the basis of a potency for crystalline sodium penicillin G at 1667 units per milligram, the theoretical potency of crystalline procaine penicillin G would be 1041 units per milligram. The

solubility of this salt in water has been found to be about 7000 units per cubic centimeter. This is in marked contrast to the solubility of the sodium and potassium salts of penicillin G. Since procaine hydrochloride and sodium penicillin G combine on a molecule-to-molecule basis, each milligram of procaine penicillin G is equivalent to 0.42 mg of procaine base. The amount of salt, therefore, possessing an activity of 300,000 units contains about 120 mg of procaine base.

The activity of procaine penicillin *in vitro* and its pharmacology in laboratory animals has been defined by Hobby et al.<sup>2</sup> The antibacterial spectrum was shown to be qualitatively similar to that of the water-soluble salt, although quantitative differences were observed in that all the bacteria tested were slightly more sensitive to crystalline sodium penicillin G than to crystalline procaine penicillin G. The latter was shown to be a highly effective agent in controlling experimental pneumococcal and streptococcal infections in mice.

The purpose of this report is to present pharmacologic data concerning the use in man of crystalline procaine penicillin G suspended in oil

### MATERIALS AND METHODS

#### *Antibiotic Agents*

Crystalline procaine penicillin G suspended in vegetable oil was available in a concentration of 300,000 units per cubic centimeter.\* Sesame oil was employed almost uniformly although a small number of observations were made after the injection of preparations suspended in cottonseed oil. All preparations were quite fluid at room temperature.

#### *Method of Administration*

The following single intramuscular injections were employed: 1 cc of procaine penicillin G in oil — 300,000 units per cubic centimeter, and 2 cc of procaine penicillin G in oil — 300,000 units per cubic centimeter.

A uniform suspension, obtained by vigorous shaking for at least two minutes, was withdrawn from rubber-capped bottles into a dry, sterile 2-cc to 5-cc syringe through a dry, sterile 18-gauge needle, which was replaced by a 20-gauge needle for injection. The mixture was injected in the conventional manner, the needle being inserted with an empty, dry, sterile syringe with which it was possible to ascertain that the needle was not in a blood vessel. Administration of the mixture in disposable cartridges containing 1 cc was performed without difficulty.

#### *Experimental Subjects*

Adult male and female human subjects were used who presented no evidence of impaired cardiac, renal or hepatic function. Post-partum female patients and young adults recovering from acute illnesses were in preponderance. In a number of cases the preparations were employed in the treatment of various acute illnesses as the definitive form of therapy.

#### *Determination of Serum Penicillin Concentrations*

The serum penicillin concentrations were determined by the method described by Rammelkamp,<sup>3</sup> using a beta-hemolytic streptococcus as the test organism.

### RESULTS

#### *Administration of 300,000 Units of Crystalline Procaine Penicillin G in Oil*

Fifty-seven subjects received intramuscularly 1 cc of sesame oil containing 300,000 units of crystalline procaine penicillin G. The serum concentrations of penicillin during the forty-eight hours following administration of this dose are shown in Figure 1. In

19 cases the concentration was determined half an hour after administration and varied from 0.04 to 0.64 units per cubic centimeter of serum. Of the 19 determinations, 16 (84 per cent) were 0.08 units per cubic centimeter or greater, and 9 (47 per cent) were 0.32 units or more. In the subjects in whom serum penicillin concentrations were determined at half an hour and four hours after injection the maximum level occurred uniformly at four hours and varied from 0.08 to 2.5 units per cubic centimeter of serum. The maximum level obtained after a given injection persisted for twelve hours in only 2 cases. Twelve hours after this injection all subjects had demonstrable concentrations of penicillin in the serum, and 34 patients (72 per cent) had levels of at least 0.08 units per cubic centimeter of serum. Assayable amounts of penicillin were present twenty-four hours

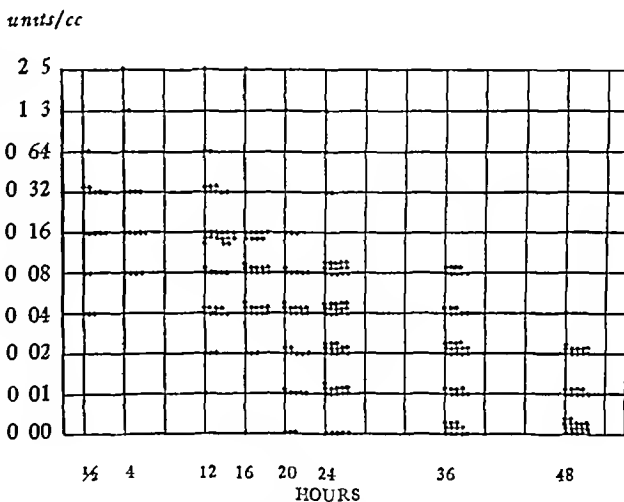

FIGURE 1. Serum Penicillin Concentrations Following the Administration of 300,000 Units of Crystalline Procaine Penicillin G in 1 cc of Sesame Oil

after administration in 58 of 63 patients (92 per cent). Forty-eight hours after administration 21 subjects (55 per cent) had assayable concentrations of serum penicillin.

#### *Administration of 600,000 Units of Crystalline Procaine Penicillin G*

Forty-eight subjects received intramuscularly 2 cc of sesame oil containing 600,000 units of crystalline procaine penicillin G. The serum penicillin concentrations present in these patients during the forty-eight hours following administration are shown in Figure 2. Half an hour after administration the serum contained 0.02 to 1.30 units per cubic centimeter of serum. Sixteen patients (80 per cent) had serum penicillin concentrations of 0.08 units or greater, and 10 patients (50 per cent) concentrations of 0.32 units per cubic centimeter of serum or greater. In all but 2 subjects from whom specimens were so taken the maximum serum con-

lonely islands in motorboats, still know their patients as their friends. One of them told me recently that he was still delivering babies on wide-leaved kitchen tables and that he still sometimes resorted to a feather stuck in the patient's nose to induce helpful sneezings. And Dr. Otis Littlefield, who died six years ago at over eighty, full of years and good works, told me a short time before his death, with pardonable pride, that over a practice of fifty years he had brought nearly 1000 babies into the State of Maine and had never lost one of them—or a mother. Quite a record for a country doctor.

Thus is Maine today not bereft of her country doctors. In a State almost wholly rural, except for four or five considerable cities and towns, the doctors are general practitioners rather than specialists, although we boast of some eminent specialists and surgeons also in our hospitals and our cities. We are proud, too, of our small hospitals as well as of our large ones in Portland, Bangor and Lewiston. In my native village of Blue Hill we have a small but beautifully equipped hospital under the able charge of Dr. Raymond Bliss, who for twenty-five years has had an eminent name as a skillful surgeon as well as a general practitioner. Many of our summer residents on the coast, who have been most generous with financial help in building our hos-

pitals, show their confidence in our Maine village doctors and dentists by coddling along their ailing teeth, their appendixes and their gall bladders until the summer comes and they can have their earthly tabernacles depleted, renovated or refurnished by our country dentists and doctors. Our Maine country doctors still have time for their patients' troubles as well as for their bodily ills, and they are still looked up to and honored by us all.

I should like to say a few words in closing—making myself for the moment as spokesman for our small Coast hospitals and our village doctors—in gratitude for a service given here from 34 Bennet Street under the Bingham Foundation. I am told by Maine doctors that the courses given under this Foundation to doctors and technicians is the greatest single help the doctors in Maine have ever had, services that have inestimably benefited the Maine physicians, laboratory technicians and hospitals, and therefore Maine people at large. For this the doctors and the people of the State of Maine are grateful to the State of Massachusetts—states that, until 1820, were both the State of Massachusetts and, even today, in the character of their people, in their coastlines, and in their country villages and their country doctors, are still one and the same.

## SERUM CONCENTRATIONS OF PENICILLIN FOLLOWING THE ADMINISTRATION OF CRYSTALLINE PROCAINE PENICILLIN G IN OIL\*

WILLIAM L. HEWITT, M.D.,† PHILIP WHITTLESEY, M.D.‡ AND CHESTER S. KEEFER, M.D.§

BOSTON

THE use of peanut oil and beeswax suspensions of amorphous calcium penicillin and of the sodium and potassium salts of crystalline penicillin G for delaying its absorption when injected intramuscularly is well known. The recent preparation of the crystalline procaine salt of penicillin G has afforded the opportunity for studying the absorption of a relatively insoluble salt.<sup>1,2</sup> Procaine penicillin is a true salt derived by the stoichiometric combination of procaine hydrochloride and sodium penicillin G. Calculated on the basis of a potency for crystalline sodium penicillin G at 1667 units per milligram, the theoretical potency of crystalline procaine penicillin G would be 1041 units per milligram. The

solubility of this salt in water has been found to be about 7000 units per cubic centimeter. This is in marked contrast to the solubility of the sodium and potassium salts of penicillin G. Since procaine hydrochloride and sodium penicillin G combine on a molecule-to-molecule basis, each milligram of procaine penicillin G is equivalent to 0.42 mg of procaine base. The amount of salt, therefore, possessing an activity of 300,000 units contains about 120 mg of procaine base.

The activity of procaine penicillin *in vitro* and its pharmacology in laboratory animals has been defined by Hobby et al.<sup>2</sup> The antibacterial spectrum was shown to be qualitatively similar to that of the water-soluble salt, although quantitative differences were observed in that all the bacteria tested were slightly more sensitive to crystalline sodium penicillin G than to crystalline procaine penicillin G. The latter was shown to be a highly effective agent in controlling experimental pneumococcal and streptococcal infections in mice.

after administration in 58 of 63 patients (92 per cent) Forty-eight hours after administration 21 subjects (55 per cent) had assayable concentrations of serum penicillin

Administration of 600,000 Units of Crystalline Procaine Penicillin G

Forty-eight subjects received intramuscularly 2 cc of sesame oil containing 600,000 units of crystalline procaine penicillin G The serum penicillin concentrations present in these patients during the forty-eight hours following administration are shown in Figure 2 Half an hour after administration the serum contained 0.02 to 1.30 units per cubic centimeter of serum Sixteen patients (80 per cent) had serum penicillin concentrations of 0.08 units or greater, and 10 patients (50 per cent) concentrations of 0.32 units per cubic centimeter of serum or greater In all but 2 subjects from whom specimens were so taken the maximum serum con-

\*We are indebted to Eli Lilly and Co., Indianapolis, Indiana; Charles Pfizer and Co., Brooklyn, New York; and Schenley Laboratories Incorporated, New York City, for supplying the crystalline procaine penicillin G in oil employed in these studies.

centration occurred four hours after administration. The penicillin concentration in 1 patient was less than and in another was the same half an hour after injection as that at the four-hour interval. The maximum serum concentration obtained with this dosage varied from 0.08 to 2.5 units per cubic centimeter of serum. The maximum level that occurred in a given subject during the first four hours following injection was present twelve hours after the administration in 12 of 31 cases. The serum concentrations of penicillin twelve hours after injection of this dose varied from 0.04 to 1.30 units per cubic centimeter of serum. Twenty-four hours after injection a concentration of 0.02 units or more was maintained in all cases. Forty-one patients (85 per cent) showed 0.08 units, and 15 patients (31 per cent) maintained 0.32 units per cubic centimeter. Forty-eight hours

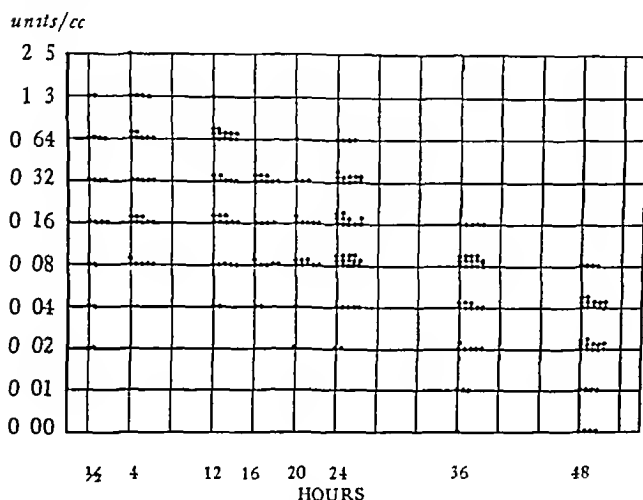

FIGURE 2 Serum Penicillin Concentrations Following the Administration of 600,000 Units of Crystalline Procaine Penicillin G in 2 cc of Sesame Oil

after administration 32 patients (89 per cent) had assayable serum penicillin concentrations, 28 patients (78 per cent) 0.02 units per cubic centimeter or more, and 4 patients (11 per cent) 0.08 units per centimeter or greater.

#### Local Reactions

Administration of this material was easily performed in the conventional manner, provided the suspension was thoroughly and vigorously shaken prior to withdrawal from the bottle. Delay in carrying out the injection after withdrawal of the preparation into a syringe resulted in early separation of the suspension and clogging of the injecting needle. There was an almost complete absence of pain at the site of injection, and subjects who had the opportunity to compare the local reaction with peanut oil and beeswax mixtures reacted uniformly in favor of the former. In only 1 of the group of 111 subjects who received well over three hundred injections was a persistent nodule palpable at the site of administra-

tion, probably owing to administration of the mixture subcutaneously instead of intramuscularly. No allergic reactions were noted.

#### Discussion

The serum penicillin concentrations following the injection of 300,000 and 600,000 units of procaine

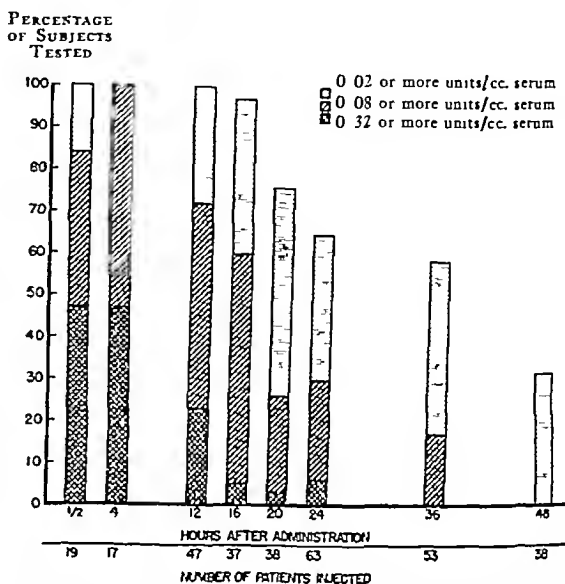

FIGURE 3 Incidence of Given Serum Penicillin Concentrations Following the Administration of 300,000 Units of Crystalline Procaine Penicillin G in 1 cc of Sesame Oil

penicillin are summarized in Figures 3 and 4. A comparison of the concentrations obtained in this

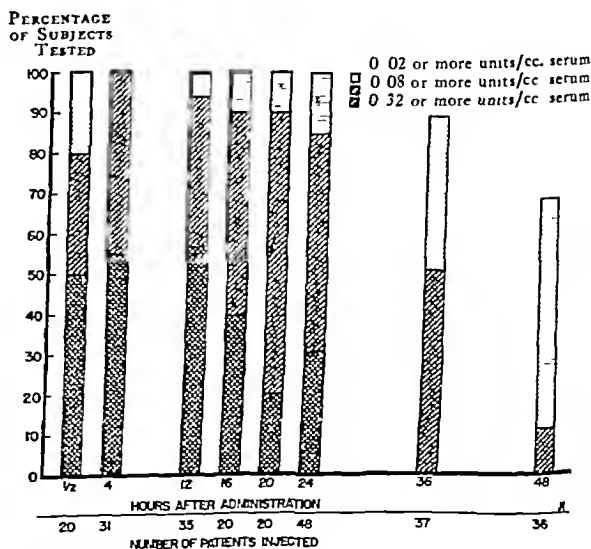

FIGURE 4 Incidence of Given Serum Penicillin Concentrations Following the Administration of 600,000 Units of Crystalline Procaine Penicillin G in 2 cc of Sesame Oil

laboratory with procaine penicillin G in sesame oil and crystalline sodium penicillin G in peanut oil and

beeswax is made in Table 1.<sup>4</sup> In contrast to the peak levels obtained after the injection of peanut oil and beeswax mixtures, there is a distinct tendency for the concentrations of penicillin to rise more slowly after the administration of procaine penicillin G. The four-hour levels were higher than those obtained half an hour after administration. The maximum serum penicillin concentrations obtained after the administration of procaine penicillin G are distinctly lower than those that follow the administration of the same dose of peanut oil and beeswax mixtures of crystalline sodium or potassium penicillin G.

tion during the twenty-four hours following administration,<sup>4</sup> the result of increased dosage of crystalline procaine penicillin G is largely one of prolongation of an effective concentration rather than an increase in the magnitude of the level during the four hours following administration. The superiority of procaine penicillin G in oil over crystalline sodium penicillin G in peanut oil and beeswax for maintaining an effective serum penicillin concentration for a period of twenty-four hours after administration is evident from the data presented in Table 1. The effective concentration varies with the infecting bac-

TABLE 1. *A Comparison of the Serum Penicillin Concentrations Following the Administration of Crystalline Sodium Penicillin G in Peanut Oil and Beeswax (POB) and Crystalline Procaine Penicillin G in Oil (PP)*

Dose	No of Patients		Interval after Administration	Serum Penicillin Concentrations			
	PP	POB		PP 0.08 unit/cc or over	POB	PP demonstrable	POB
600,000 units	35	30	12	94	90	100	100
	48	31	24	85	52	100	84
	57		36	51		97	
	36		48	11		89	
	47	30	12	72	70	100	93
300,000 units	63	20	24	10	10	92	70
	53		36	17		74	
	38		48	0		55	

Thus, the maximum concentrations obtained after the administration of 1 cc of peanut oil and beeswax containing 300,000 units of crystalline sodium penicillin G varied from 0.08 to 5.0 units per cubic centimeter of serum as compared with concentrations varying from 0.04 to 0.64 unit after the administration of a similar dosage of crystalline procaine penicillin G in sesame oil. Even more striking is the range of maximum penicillin concentration following the administration of 600,000 units. With the peanut oil and beeswax mixtures the concentration varied from 0.63 to 20 units per cubic centimeter of serum, whereas a concentration of 0.08 to 2.5 units followed the injection of the same amount of procaine penicillin G. There is a tendency, particularly with a dosage of 600,000 units, for the serum penicillin concentrations to be more uniform during the first twenty-four hours following injection of procaine penicillin G than sodium penicillin G in peanut oil and beeswax. It appears reasonable to assume that the difference in solubility of these two salts of penicillin is at least a major factor in producing this characteristic difference. The influence of solubility as a limiting factor may be further manifest in the comparison of the serum penicillin concentrations obtained with a dosage of 300,000 and 600,000 units. Whereas a dosage of 600,000 units of crystalline sodium penicillin G in peanut oil and beeswax produces a considerable increase in the magnitude of the serum penicillin concentrations during the first four hours after injection, as well as an increased incidence of an effective serum penicillin concentra-

tion and character of the infectious process present. Thus, while the penicillin concentrations required for the treatment of most of the infections caused by the gonococcus, alpha-hemolytic and beta-hemolytic streptococcus and the pneumococcus fall within the ranges obtained in this study, higher penicillin concentrations than can be obtained with this preparation may be necessary for the treatment of overwhelming infections, bacterial endocarditis, chronic osteomyelitis and infections due to organisms of high penicillin resistance, such as certain staphylococci. It is conceivable that under some circumstances the higher penicillin concentrations that result intermittently from the administration of crystalline sodium penicillin G in peanut oil and beeswax mixture might make this preparation more effective than procaine penicillin, with which an effective level was not obtained even intermittently.

Another advantage of procaine penicillin G in oil for prolonging therapeutic blood levels of penicillin over peanut oil and beeswax preparations is the elimination of beeswax, which has been cited as a cause of a number of unfavorable local reactions. The local reactions following the administration of procaine penicillin were significantly less than those that followed the use of peanut oil and beeswax.

Allergic reactions after the administration of penicillin in peanut oil and beeswax are higher than those following the use of aqueous penicillin. The incidence of such reactions after administration of procaine penicillin in oil remains to be determined. The activity of procaine penicillin G presumably depends

upon the dissociation of the molecule into its respective members, and patients who are allergic to penicillin or to procaine will probably be sensitive to this preparation. The toxicity of procaine itself is of interest in this regard inasmuch as some persons are hypersensitive to this agent. Furthermore, the toxicity of procaine penicillin G is determined by the amount of procaine base present in the compound.<sup>2</sup> This conforms to previous studies with soluble salts of penicillin in which it was shown that the toxicity of various salts was determined by the cation present.<sup>5</sup> Three hundred thousand units of procaine penicillin G contains approximately 120 mg of procaine base. Toxicity to procaine is dependent upon its rate of absorption and its concentration.<sup>6</sup> Inasmuch as the absorption of procaine penicillin into the circulation is so slow, it is unlikely that appreciable amounts of procaine would be present after the administration of therapeutic doses of procaine penicillin G. An intradermal sensitivity test with 1 per cent procaine solution should, however, be performed when suspicion of procaine allergy exists.

#### SUMMARY

Administration of 300,000 units of crystalline procaine penicillin G in sesame oil produced demonstrable serum penicillin concentrations at twelve hours after administration in all and at twenty-four hours after injection in 92 per cent of subjects studied.

Administration of 600,000 units of this material produced demonstrable serum penicillin concentrations twenty-four hours after injection in all and at

forty-eight hours after injection in 89 per cent of subjects studied.

The maximum serum penicillin concentrations obtained with procaine penicillin G in oil were distinctly lower than those following a similar dose of sodium penicillin G in peanut oil and beeswax. The concentrations following administration of the former preparation, particularly with a dose of 600,000 units, showed considerably more uniformity throughout the twenty-four hours following injection.

A comparison of the serum penicillin concentrations obtained after a dose of 300,000 and 600,000 units of procaine penicillin G revealed the most characteristic difference to be a prolongation of a given effective penicillin level rather than an increase in the magnitude of the penicillin concentration during the early period after administration.

Crystalline procaine penicillin G in oil was superior to crystalline sodium penicillin G in peanut oil and beeswax for maintaining an effective serum penicillin concentration for twenty-four hours after injection.

We are indebted to Miss Doris McCarthy for technical assistance.

## PAROXYSMAL HYPERTENSION IN SPINAL-CORD INJURIES\*

CHARLES E THOMPSON, M D,<sup>†</sup> AND CAPTAIN A CALHOUN WITHAM, M C, A U S<sup>‡</sup>

MEMPHIS, TENNESSEE

THE purpose of this paper is to report on the clinical significance of a little known, but constantly occurring, phenomenon in high spinal-cord lesions. Mass sympathetic discharge, occurring either in conjunction with "mass reflex" or alone in response to various stimuli, has been noted for many years and was first clinically recorded in the classic papers of Head and Riddoch.<sup>1</sup> Since sweating is the most obvious manifestation of this activity, the mass sympathetic discharge has usually been incompletely designated and has received much attention as "spinal reflex sweating."<sup>2</sup> That the vasomotor component and in particular the severe hypertension may well be the most important part of the syndrome from the standpoint of managing the patient is pointed out below.

The trigger mechanisms that set off the general sympathetic response may be summarized briefly in the words of Head,<sup>1</sup> the first to describe it: "There is scarcely a stimulus, cutaneous, proprioceptive or visceral, that may not be followed by an outburst of sweating appropriate to the lesion in each case." Distention of the bladder, and sometimes of the rectum, has been universally the most common cause in the experience of all.<sup>1-3</sup> The syndrome is manifested by excessive sweating, flushing of the face, congestion of the nasal passages, pilomotor erection, sometimes shivering and a feeling of dullness in the head, which may progress to a severe, throbbing, bitemporal, occipital or frontal headache. Blurring of vision is not uncommon. Objectively the pulse may become slow, irregular and more forceful. The blood pressure climbs almost immediately to precipitous heights, and, if the stimulus is continued, convulsions and loss of consciousness may occur. These changes are quickly reversible when the offending stimulus is removed. Details of the sweating have been adequately described elsewhere.<sup>2</sup> This discussion is confined to the description of accompanying hypertension, which we believe to have been neglected as a field of study. Recent American reviews of the treatment of various stages of paraplegia, or observations of the related sympathetic phenomena, do not mention its occurrence.<sup>3-5</sup> Physicians who have spent much time with paraplegic patients have noted, however, that fluctuations of blood pressure are not uncommon although they

have observed no particular pattern to these variations. It appears from our studies that these wide variations in blood pressure are an integral part of a sympathetic response to various stimuli, principally vesicular and rectal in origin. This response has been described as being a component of the mass spinal reflex,<sup>2</sup> a release phenomenon induced by any afferent stimulus acting on the distal portion of the cord, the efferent path being through the thoracolumbar outflow of the autonomic system.

While our work was under way, Whitteridge and Guttmann,<sup>9</sup> who had previously made independent observations along the same lines, published a summary of their studies indicating a profound redistribution of blood flow. This might have been suspected from clinical observations. These authors noted greater blood-pressure changes when the cord lesion was above the level of the sixth dorsal segment. This fact they attributed to an inability of the organism to compensate by selective redistribution of blood flow when the large splanchnic bed was cut off from control of the vasomotor center. Changes in blood flow of the extremities in response to various nociceptive stimuli occur in normally innervated people.<sup>10</sup> Distention of the viscera in normal people also causes vasoconstriction in the fingers and toes.<sup>11</sup> A brief summary of the work of Whitteridge and Guttmann<sup>9</sup> follows.

In lesions above the sixth dorsal segment they noted a slight rise in rectal temperature and a greater rise in skin temperature of the neck and ears upon bladder distention. As measured plethysmographically, there was a decrease in volume of fingers and toes. There was an initial sharp decrease in pulse rate followed by a normal rate as bladder pressure was maintained. Pulse volume and temperature increased in the ears, meanwhile, temperature of the lower extremities fell.

In lesions below the sixth dorsal segment they found the same fall in temperature of the lower extremities combined with a profound fall in pulse volume of toes, but the blood flow increased in fingers and the blood pressure rose no more than 30 mm in contrast to increases of 100 mm or more in the higher lesions. They concluded that in the lower lesions there were still splanchnic areas under vasomotor center control available for compensatory vasodilatation. Distention of the rectum caused a similar syndrome, but the effects were more transient.

We have confirmed these observations with the exception of the plethysmographic recordings, which we were unable to do at this hospital. Typical experimental studies at various levels of the spinal-cord injury are discussed below.

### METHOD

The patients were placed in recumbent position, and a tidal drainage apparatus with a cystometric manometer attached to a No. 16 Foley catheter

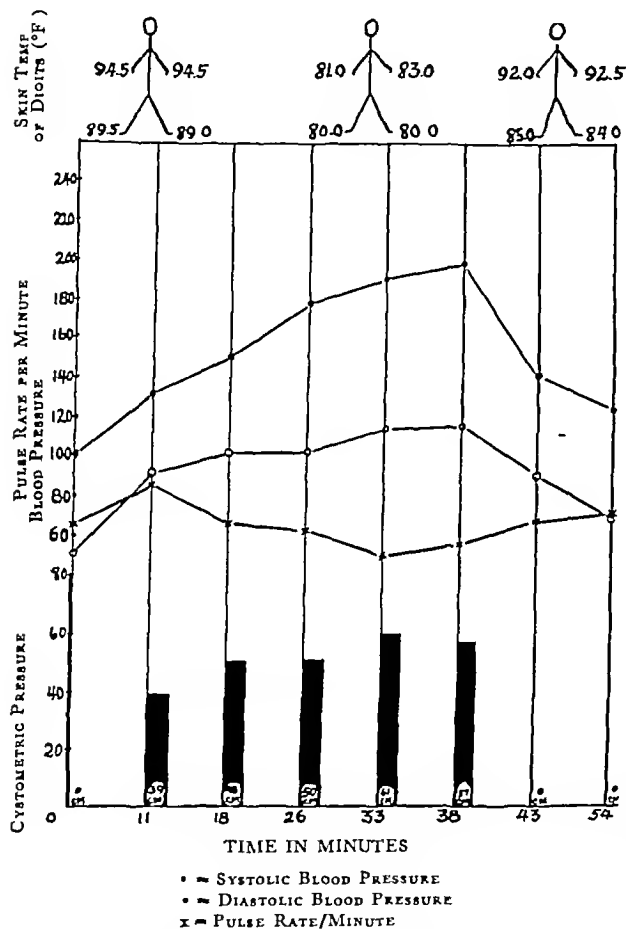

FIGURE 1 Pertinent Data in Case 1

previously inserted into the bladder. Skin temperatures were measured directly by a thermocouple (U.M.A. corporation). The subject was placed in a thermostatically controlled room at a constant temperature of 70 to 72°C for an hour before the procedure, to permit the skin temperature to become stable. Readings were made from the palmar surfaces of the distal phalanges of several digits of each extremity. Since no essential difference in direction of change occurred among the several digits of any one extremity, the first digit was arbitrarily chosen to be used in the illustrations. Blood pressures were measured indirectly by a cuff and mercury manometer. On certain patients, electrocardiographic and oscillometric records were taken. Observations were made of the blood pressure, pulse

rate, gross sweating, pilomotor changes and skin temperatures as the bladder was slowly filled with an irrigating solution ("G solution").<sup>12</sup> Subjective sensations, such as headache, palpitation, rigor and flushing were noted.

The following case reports are illustrative of the type of blood-pressure response that may be experimentally produced by distention of the bladder at the various levels of spinal-cord injury.

**CASE 1** E. J. C., a 22-year-old man, with traumatic transverse myelitis of 40 months' duration, had a physiologically complete lesion at the level of the fifth cervical segment. He gave a history of spinal sweating, headache and sometimes convulsions of short duration associated principally with urinary-tract infections while he was at another hospital. The blood pressure was not recorded at that time, and no cause for the convulsions was found. The attacks subsided spontaneously when the infections had ended. The blood pressure, cystometric pressure, pulse rate and skin temperatures of the digits are shown in Figure 1. For the last few months the patient has been symptom free.

During this procedure, although no convulsion occurred, the patient stated that the headache and chilliness that appeared with the rise in blood pressure were similar to his difficulties some months previously, which had sometimes caused loss of consciousness and generalized convulsions of a few minutes' duration.

**CASE 2** H. R., a 22-year-old man, with traumatic myelitis incurred in June, 1945, had a lesion neurologically complete at the level of the seventh dorsal segment and had exhibited

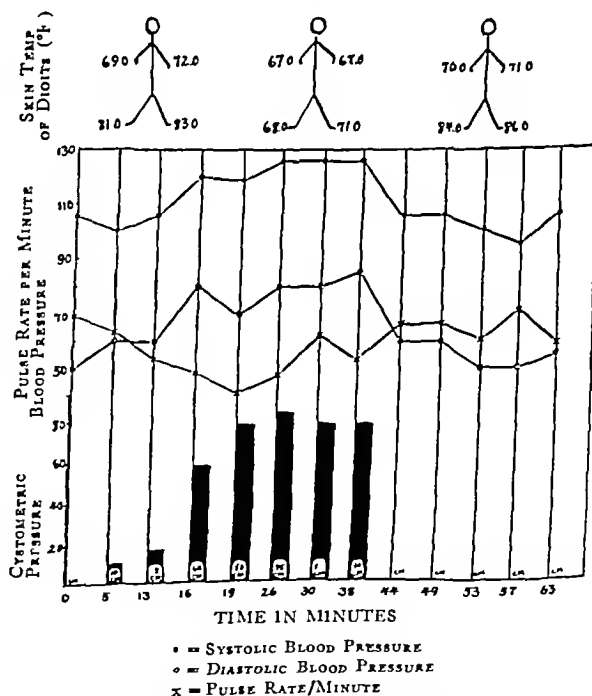

FIGURE 2 Pertinent Data in Case 2

reflex sweating since a few weeks after injury. He had had no cerebral symptoms. Laminectomy done in June, 1947, demonstrated a complete absence of the cord at the level of the seventh dorsal segment. The blood pressure, cystometric pressure, pulse rate and skin temperatures of the digits are shown in Figure 2.

Bladder sensation was completely absent in this patient. The appearance of sweating and pilomotor erection was prompt and severe on both legs but predominantly right-sided.

on the trunk as high as the level of anesthesia. Dermographia was striking above and below the sensory level, whereas the bladder pressure was high and disappeared promptly when pressure was released.

**CASE 3** G. L., a 31-year-old man, with incomplete transverse myelitis at the level of the second lumbar segment of 19 months' duration, had developed an automatic bladder but had never noticed the sympathetic discharges associated with distended bladder in patients with higher lesions. Thermoregulatory sweating was normal above and below the

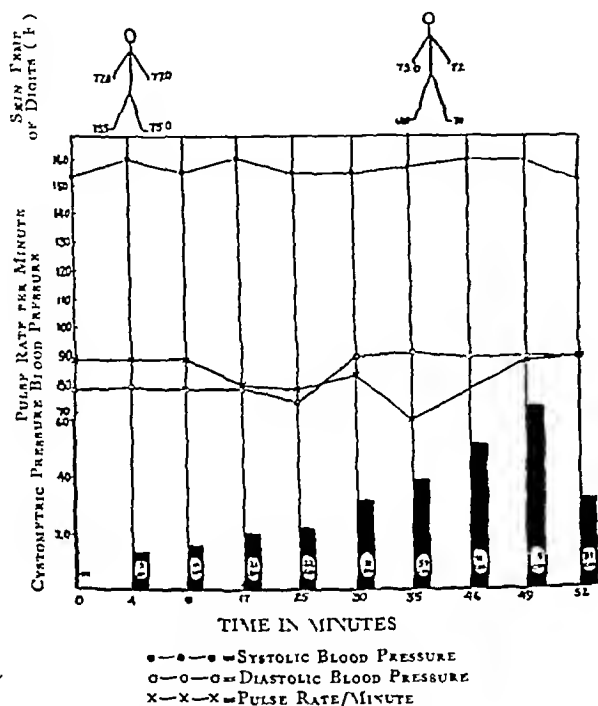

FIGURE 3 Pertinent Data in Case 3

lesion. The blood pressure, cystometric pressure, pulse rate and skin temperatures of the digits are shown in Figure 3.

In this patient, the central pathways of the autonomic system were apparently undamaged. No spinal sweating, pilomotor phenomena or hypertension occurred although from the skin-temperature changes, it seemed that vasoconstriction was taking place in the extremities although the systemic arterial pressure remained essentially the same. This case illustrates the effect of bladder distention in a patient with an intact autonomic nervous system.

In the following cases the vasomotor disturbances were of clinical importance in the care of the patient.

**CASE 4** E. D., a 22-year-old man, with a physiologically incomplete lesion below the level of the fifth cervical segment, since July, 1946, had the following interesting history. A few weeks after traumatic spinal-cord injury, not involving the head, the patient began to have periods of dimness of vision, sometimes severe headache with loss of consciousness and clonic movements of the left upper extremity and facial musculature. In retrospect the patient associated these "attacks" with change of catheter, sudden changes of position and enemas. Complete initial study failed to assign an etiology to this syndrome although electroencephalographic findings suggested "a focus of activity in the right fronto-temporal region without seizure discharges." Consultation with the ophthalmologist revealed normal funduscopic findings. "Seizures" were interpreted as epileptiform or its equivalent. There was no other neurologic evidence of intracranial disease. In April, 1947, a suprapubic cystostomy was performed because of postoperative hemorrhage following a litholapaxy. There was a complete and dramatic cessation

of these attacks. Repeat electroencephalogram showed no essential change from the previous record.

In retrospect, the possibility that these symptoms were produced by bladder spasm was considered after the patient had been symptom free for 8 months with the suprapubic tube in situ. Consequently we attempted to reproduce these symptoms experimentally by the methods outlined above. The blood pressure promptly rose to 220/115 when a pressure of 90 cm of water was present in the bladder. The usual autonomic phenomena were noted, and in addition, the pupils became bilaterally dilated, more so on the left. The patient complained of dimness of vision and headache and the facial muscles began to twitch. As the patient began to lose consciousness and became cyanotic, the bladder pressure was released. The patient's symptoms promptly disappeared in 3 minutes, and the blood pressure fell to 110/60 — his basal reading.

**CASE 5** T. B., a 25-year-old man with an incomplete lesion at the level of the fifth cervical segment since September 11, 1946, experienced sudden throbbing, bitemporal headache with flushing of the face, pilomotor erection, excessive sweating and symptoms of mental confusion and loss of consciousness each time an enema was administered. Other stimuli such as bladder distention and sudden changes in position from recumbent to upright and turning on the face, invoked the same chain of events innumerable times during the day and night. The symptoms had become more frequent and severe during the last few months. Blood pressures recorded during these attacks consistently ranged as high as 260/140. (This patient had undergone a progressive deterioration of mental outlook because of despair over this severe, additional incapacity.) Tetraethyl ammonium chloride, administered before these procedures, consistently prevented the attacks. This effect was maintained for less than 1 hour, however, and on account of the severity, frequency and persistence of the symptoms, a surgical attack on the sympathetic ganglions is being considered.

**CASE 6** W. H., a 22-year-old man with incomplete paraplegia below the level of the third dorsal segment, was first

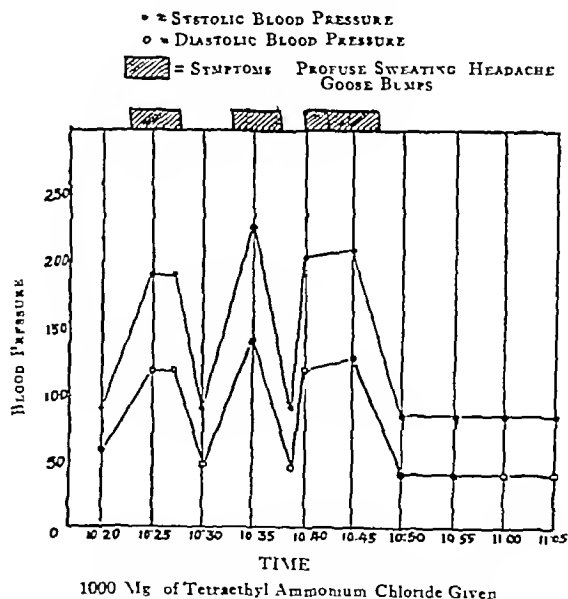

FIGURE 4 Effect of Tetraethyl Ammonium Chloride in Case 6

afflicted with excruciating, throbbing, bitemporal headache with the attending evidence of sympathetic discharge while suprapubic cystostomy was being performed. For several days postoperatively the same syndrome occurred every 15 or 20 minutes during the day — somewhat less frequently at night. This was always associated with severe bladder spasm that blocked the urinary outflow at the catheter but subsided spontaneously when flow was re-established. The blood pressure rose as high as 220/140 from a basal pressure of 90/70. Tetraethyl ammonium chloride intramuscularly in a dose of

0.8 to 1.0 gm dramatically stopped the headache, lowered the blood pressure and abolished the sweating. The patient usually remained symptom free for 4 to 6 hours after injection of the drug, in spite of persistent bladder spasm obstructing the free flow of urine, although spasms were less frequent. After 4 days the bladder spasms became so infrequent that the use of the drug was no longer necessary (Fig 4).

These blood-pressure recordings were made on the 3rd postoperative night, and the frequency of attacks had gradually increased until one had barely ceased when another occurred.

### CLINICAL SIGNIFICANCE OF THE HYPERTENSIVE COMPONENT

Since the blood pressures are more labile in lesions above the level of the fifth dorsal segment and since these patients usually have more complications that can provoke the reaction, the hypertension and its concomitant symptoms obviously play a more significant role in this type of case.

The appearance of severe, intermittent headache in high cord lesions should cause the physician to note whether or not this often easily recognizable series of events is in progress. Attention should immediately be directed to the bladder or bowel. The observation has been repeatedly made that blocking of a catheter, acute genitourinary infections and distention of the bowel are attended by hypertension and its concomitants. It should be pointed out that the intracerebral vasomotor change may progress to loss of consciousness and occasionally to the convulsive state, as in Cases 1, 4 and 5. On occasion this may simulate organic brain disease, as in Case 4.

It may easily be seen that the instability of blood pressure in high cord lesions may assume importance in surgical procedures. Paroxysmal hypertension during operation not infrequently taxes the ingenuity of surgeons in control of hemostasis. This is particularly true in resection of hypertrophic bladder neck when the bladder is mechanically distended by hydrostatic pressure. During long operative procedures care should be taken that the bladder does not overdistend. Distention of the bladder sometimes accounts for the hypertension seen toward the end of long plastic and orthopedic procedures in high cord lesions. There is some evidence that a postoperative cerebrovascular accident is provoked by this mechanism.

### TREATMENT

The obvious treatment is removal of the stimulus but this is often impossible, as in Case 4, in which the administration of an enema became an extremely painful process. It is for such patients that we began to search for an agent to block the reflex. Tetraethyl ammonium chloride (Parke-Davis)<sup>13</sup> has admirably filled this need, as indicated in Figure 4. This experience has been duplicated repeatedly in natural and artificially induced attacks. None of the usual sedatives and analgesics had any noticeable effect. In some patients as little

as 400 mg of tetraethyl ammonium chloride, administered intramuscularly, was immediately effective although for a much shorter time than with larger doses.

Preliminary, and as yet incomplete, studies with paravertebral procaine blocks indicate that bilateral lumbar sympathetic blocks are insufficient to stop the reflex. Relatively small amounts of procaine injected in the lumbar subarachnoid space, however, were effective in 2 cases.

In only 1 patient were symptoms sufficiently severe, prolonged or frequent for sympathectomy to be considered. Successful segmental sympathectomy for excessive spinal reflex sweating has been done,<sup>2</sup> but its effect on the paroxysmal hypertension has not been recorded. We suspect, however, that in these few cases an extensive procedure of the Smithwick type should be considered.

### SUMMARY

Attention is called to the phenomenon of paroxysmal hypertension associated with mass sympathetic discharge in high cord lesions. We have confirmed certain aspects of recent studies regarding the accompanying vasomotor changes. The diagnostic and therapeutic importance of this syndrome is emphasized. Tetraethyl ammonium chloride is an effective drug in its symptomatic control. The possibility that an occasional patient may require surgical sympathectomy for relief of symptoms is proposed. A few typical cases are presented. The controversial physiologic interpretations are not discussed. A number of lines of investigation suggest themselves. These include the effect of autonomic drugs and further studies of the hemodynamics.

## PUBLIC HEALTH TODAY AND TOMORROW IN MASSACHUSETTS\*

V A GETTING, M D , D R P H T

BOSTON

PUBLIC health is primarily the responsibility of state and local governments. This responsibility, however, must be shared by the medical profession and hospitals if the benefits from recent advances in the medical sciences are to be extended to all the people. For over seventy-five years the Massachusetts Department of Public Health has been serving the people of the Commonwealth in an effort to prevent disease, prolong life and promote optimal health. Almost a hundred years ago Lemuel Shattuck, alarmed at the unusually high death rate among those in the prime of life in the Commonwealth, conducted a sanitary survey. Shocked by the untimely deaths of the inhabitants, he realized that the essentials required for healthful living should be made available to all people. Nineteen years later this survey culminated in the creation of the first state department of health. The Massachusetts Medical Society vigorously supported the creation of the Department and throughout the ensuing years has co-operated in the extension and improvement of public-health services in the Commonwealth.

## PUBLIC HEALTH TODAY

The evolutionary development of the Department from the small nucleus of 1869 has been a gradual but constant process. Today, it employs approximately 1,800 people and expends an annual appropriation of approximately \$7,250,000. In addition to its other activities, the Department is responsible for the operation of five institutions, eight branch offices and seven laboratories. The federal Government, recognizing its responsibility in the general welfare of the people, annually makes available to Massachusetts approximately \$2,500,000 through grant-in-aid programs.

Both the scope and the character of the work of the Department have changed with the passing of years. Primarily concerned with environmental sanitation and the abatement of nuisances, the Department is now engaged in activities pertaining to all aspects of public health. These include the administration of medical care programs, administration of federal grants-in-aid for the construction of hospitals and health centers, the operation of hospitals, supervision and licensing of clinics and hospitals, epidemiology of disease, manufacture and distribution of prophylactic and therapeutic biologic products and processing and fractionation of human blood. The development and pro-

motion of programs dealing with maternal and child health, tuberculosis, venereal diseases, control of cancer and chronic diseases and the research and development of new public-health methods and technics are daily responsibilities of the Department.

*Recess Commission on Public Health*

A special commission authorized to make a study relative to certain public-health matters was established by Chapter 73 of the Resolves of 1947. This commission was charged not only with the responsibility of considering the licensing of hospitals, convalescent and nursing homes and the co-ordination of local, state and federal activities in the field of public health but also with the laws and policies of the Commonwealth relating to public health. The Commission consisted of Senator Richard H. Lee, Newton, chairman, Representative George W. Dean, Oakham, Representative Joseph D. Rivist, Northampton, Representative Fred C. Harrington, Everett, Dr. Henry D. Chadwick, Waltham, former commissioner of the Massachusetts Department of Public Health, Dr. L. Jackson Smith, commissioner of public health of Springfield, and Professor Curtis M. Hilliard, professor of public health at Simmons College and supervisor of the Board of Health of Wellesley and Weston. The report of this special commission has been published as House Document No. 1766 of the current legislative session.

The Commission organized two technical advisory committees. Dr. Hugh R. Leavell, of Cambridge, professor of public-health practice, Harvard School of Public Health, was appointed chairman of the Committee on Local Health Units, and Dr. Conrad Wesselhoef, of Boston, clinical professor of infectious disease, Harvard School of Public Health, chairman of the Committee on Preventable Diseases. These committees are continuing their work in anticipation of the continuation of the Special Recess Commission, which submitted a progress report to the legislature on December 3, 1947 (H 1766). The activities of the Commission were directed toward certain major objectives, as follows: the administrative changes in the Department of Public Health, the development of some equitable plan for the establishment of full-time health units throughout the Commonwealth in areas of such population as may be reasonably and economically administered, relocation of the chronic-disease hospital, the licensing and regulation of certain hospitals, sanatoriums and nursing homes by the

\*Presented at the annual meeting of the Middlesex South District Medical Society, Cambridge, April 21, 1948.

†Commissioner, Massachusetts Department of Public Health.

Department of Public Health, and consideration of legislation requiring the x-ray examination of schoolteachers and other school employees

The Commission employed as a consultant Dr Carl E. Buck, field director of the American Public Health Association, who, with his assistant, Dr Robert E. Rothermel, contributed valuable aid and consultative advice. The Commission requested its technical advisory committee to make an extensive study of the organization of the Department and to prepare recommendations to the Commission regarding the simplification of the table of organization. As a result of this study, it was recommended by the Commission that assistant commissioners of public health be appointed who would devote their entire time to the administrative duties associated with the five major units into which the Department would be divided. The Commission recommended the consideration of reclassification of both titles and salaries of professional personnel in the field of public health. The Commission became fully cognizant of the fact that the salaries paid professional personnel in Massachusetts do not and cannot assure the people of the Commonwealth the leadership necessary to provide these basic medical services essential to the health of the people. Legislation implementing the recommendations by the Commission and by Dr Buck was introduced and is now pending in the current legislative session.

### *Local Health Services*

Perhaps the major assignment of the Commission has been the development of an equitable program for the creation of local health units throughout the Commonwealth. The greatest need in public health today in Massachusetts, as well as in the United States, is the development of full-time, adequately staffed local health departments for population groups sufficiently large to enable efficient and economic administration. A preliminary study of legislation pertaining to local health departments and unions of health departments, their duties, responsibilities and services rendered the people has been made in a report submitted. The Technical Committee on Local Health is continuing its work in this field.

Massachusetts may well take pride in the fact that in its health responsibilities, including the provision of tuberculosis hospitals, and in its vital statistics, which reveal a low infant and maternal mortality, absence of smallpox and low typhoid-fever morbidity, it compares very favorably with other sections of the country. However, the Commission has not considered that doing a good job is sufficient. Its report indicated that only the best possible public-health program should continue to evolve in Massachusetts.

Although the Commonwealth has been and is still far ahead of most of the country in such important

activities as cancer and tuberculosis control and in environmental sanitation, Massachusetts, as well as the remainder of New England, is far behind the rest of the country in the development of full-time, adequately staffed local health departments for units of sufficient population size to be susceptible of reasonably economic and efficient administration. In the Commonwealth today there are but eleven cities and towns and one county that provide full-time medical health officers not engaged in private practice. These include Boston, Brookline, Cambridge, Fall River, Falmouth, Lowell, Newton, North Adams, Pittsfield, Springfield, Worcester and Barnstable County. There are today in Massachusetts twenty communities of 35,000 population or more not served by full-time medical health officers. Such a condition exists despite the fact that practically all public-health administrators are agreed that the most important public-health need today is the development of adequately staffed full-time health departments. Dr Carl Buck, of the American Public Health Association, who has recently reviewed the status of local health services in the Commonwealth and who bases his opinion upon the "Evaluation Schedule of Local Health Services," has reported that there are but four health departments in all of Massachusetts that would be judged "good" on the basis of these accepted standards.

Why are the physicians and the people of the Commonwealth so apparently satisfied with the situation as it exists? Simply because Massachusetts rates for preventable causes of death are somewhat better than the average of the country as a whole? Perhaps this is being satisfied rather easily, for in the Commonwealth during the five-year period 1941-1945 inclusive more than 1,500 persons died from the following "preventable causes": diphtheria, 50, measles, 71, whooping cough, 142, syphilis, 1238, typhoid fever, 20, bacterial dysentery, 26, tetanus, 29, and undulant fever, 7. For the same period (1941-1945) over 70,000 deaths from controllable causes occurred as follows: cancer, 37,361, tuberculosis, 7888, lobar pneumonia, 3962, premature births, 4696, accidents, 14,670, meningitis, 279, scarlet fever, 63, maternal deaths, 934, and diarrhea and enteritis (in patients under two years of age) 693. If the knowledge concerning the prevention and control of these diseases that we have at hand could be universally applied throughout the Commonwealth, the saving in lives would be tremendous. Practically all the deaths from preventable causes could have been avoided, and it has been very conservatively estimated that at least a third of all cancer deaths and at least half of all other deaths from controllable causes could have been avoided. Thus, in Massachusetts alone, the saving of over 30,000 lives over a five-year period, or an annual saving of 6000 lives, could have been effected. If a human life is valued at only \$5000, this would result in an annual saving to the Com-

monwealth of over \$30,000,000 Obviously, the Commonwealth is currently and continuously experiencing an irreparable loss in lives and money. If the essential developments of modern medicine, preventive procedures and programs developed through public health could be made available to all the people these lives would not be lost but would continue to contribute to the assets of the Commonwealth.

In such a program the Government alone cannot succeed. The annual saving of over 6000 lives is a challenge not only to the government but also to the public-health and medical professions. Imagine the sacrifice of 30,000 people every five years in the Commonwealth — a population equivalent to that of the cities and towns of Revere, Belmont, Weymouth and Melrose! It must be borne in mind, however, that these figures represent but a portion of the entire problem. They include no estimate of the amount and extent of sickness or economic loss resulting from cases that do not terminate in death. For example, it is estimated that the annual loss of income of the Commonwealth due to disability from chronic disease is \$50,000,000. Is it a wonder then, that the medical profession and the public are expressing a growing concern about this unnecessary loss of lives and income?

Medical and other professional schools are now training physicians, dentists, nurses and health officers, in an effort to supply the personnel necessary to provide basic health services. Through local resources, voluntary and governmental hospitals and health centers are in the process of construction throughout the Commonwealth. The Department of Public Health is assisting this expansion of physical facilities through the administration of the Survey and Plan for Construction of Hospital and Health Centers in the Commonwealth. By means of this program financial assistance will be offered to some of these projects through a federal grant amounting to \$8,000,000, which will extend over five fiscal years beginning on July 1, 1947.

The greatest single need in Massachusetts, however, is the development of local health units, adequately staffed and efficiently serving all the people of the Commonwealth. If full-time health departments are to be established, certain basic essentials must be met.

A sound state-wide program of health education to accomplish as soon as possible a universal understanding of the needs and value of full-time health services.

An active department of health adequately staffed. This is essential for the proper leadership and stimulation of activities throughout the cities and municipalities.

Basic legislation permitting and facilitating the establishment of full-time health departments through unions of towns on a voluntary basis.

Approval of the state health agency of such departments would be necessary that no section of the Commonwealth would eventually be without such services. Compulsory formation of such unions may be required if they are not formed voluntarily within a period of five to ten years.

A plan for state and federal subsidy for the maintenance of full-time local health departments.

The training of adequate health officers, public health nurses, sanitarians, nutritionists and medical social workers required for the local health units.

The provision of adequate compensation to qualified public-health personnel. This is an essential, since the recruitment and retention of good personnel depend first and foremost upon good salaries, reasonable tenure of office, opportunities for advancement and reasonable plan of retirement. The last three, of course, may be effectively obtained through a well conducted civil-service system.

Periodic evaluation of services rendered by the community health agencies preferably through some method of study as that devised in the evaluation schedule of the American Public Health Association. Evaluations of this type have many uses, among them being provision of a base line for future measurement, calling attention to achievements and unmet needs, and furnishing a foundation for future planning.

Of these seven basic essentials necessary to the establishment of full-time local health departments, Massachusetts is lacking in all. Perhaps the best way of meeting the need for the dissemination of health information is through the creation of a state-wide health committee designed to achieve real understanding on the part of the people and the professions of the services and benefits that can be obtained through the extension of adequate local health services.

Although existing legislation permits the establishment of unions of towns for health purposes, such unions have not been successful in the past because of their effervescent nature and failure of financial support from either state or federal appropriations. A plan must be devised for providing various alternate methods for these unions of towns on a county or district basis, which will ensure complete coverage of the Commonwealth within a reasonable time, or the alternative of such a program must be introduced — namely, that such unions be formed after public hearings throughout the Commonwealth have been held by the Department of Public Health.

At present there are but nine states in the entire United States that do not make available state funds to local health departments. Massachusetts is one of these.

### *The Private Practitioner and the Health Department*

Efficient local health departments have always called attention to the need for more adequate medical services. It has been my experience and that of most public-health officials that the more conscious the public becomes of health, the more it utilizes available local health facilities and services. Therefore, the formation of adequately staffed health units throughout the Commonwealth would increase the utilization of services of physicians, dentists and hospitals. Although physicians may as a result of this become more overworked than they are now, such services would consist primarily of preventive measures and the diagnosis and treatment of early illnesses or disabilities rather than the providing of terminal care, which has unfortunately occurred too often. To be sure, prolonged illness and chronic disability will still occur, but effective preventive measures, early diagnosis and prompt and adequate treatment may greatly reduce the incidence.

A private practitioner of medicine has, therefore, a moral obligation to the people to assist in furthering community health programs. At the same time he will contribute to the economic improvement not only of himself but also of his entire community.

### *Long-Term Illness*

Physicians are all concerned with the task of prolonging life and improving the health of patients. Today, with the life expectancy of a newborn infant amounting to almost seventy years, the doctor's responsibility for this life is greater. With advancing age the human body tends to succumb to a host of chronic diseases, such as heart disease, vascular disease, cancer and diabetes, any one of which may be not only prolonged but also often disabling. The medical and public-health professions have made outstanding advances in the control of infectious diseases and the diseases of early life, which must continue, but they must also acquire further knowledge and develop better methods for the early diagnosis of preclinical long-term illnesses. New procedures for the prevention, early diagnosis and amelioration of chronic diseases must be the next major development. Although it may be impossible to prevent heart disease per se, it may be possible not only to reduce its incidence

but also to delay the onset of symptoms, postpone the disability period and prolong life for many productive and happy years. By similar methods, the patient with cancer or diabetes may look forward to a longer productive life. This will occur, but the essential prerequisite is that health departments and the medical profession, through co-ordinate action, make available to the people the benefits of new medical knowledge as soon as it is of proved value.

Here again the private practitioner receives a challenge — a challenge not only to promote greater health in the aging population but also to realize and accept the changing goal in his daily practice. Health supervision, through periodic, thorough examination and care of the patient, becomes a physician's increasing responsibility.

### PUBLIC HEALTH TOMORROW

The education of the patient in healthful living is the dual responsibility of the doctor and the health department. The doctor of tomorrow must not only prescribe well but also inform well. Patients want to know what can be done to improve their health. Today, more than ever before, the public is conscious of its health, people are making greater demands for services upon the Government, hospitals and the medical profession. The future of public health is therefore encouraging. Programs for the maintenance and preservation of health are both improving and increasing in scope. The people, by demanding basic health services, will secure coverage of the nation with adequately staffed local health departments. Improved facilities of hospitals and clinics, the workshops of physicians, will serve more people. The school child will be offered a better opportunity to attain adult life without physical or mental disability, and as an adult, he will be convinced that good health cannot be taken complacently but can be assured only through diligent care under the direction of competent physicians.

Thus, by striving toward the common objective of improving the health of the people the doctor, hospital and health officer may bring to every person the basic essentials, diagnostic, preventive and therapeutic measures that will enable him to enjoy a more productive life and become a greater asset to the community.

## MEDICAL PROGRESS

## CHEMOTHERAPY OF NEOPLASTIC DISEASE

## III. Agents of Clinical Value

DAVID A. KARNOFSKY, M.D.\*

NEW YORK CITY

From the large array of substances under laboratory and clinical study, several have been established as useful in the management of patients with inoperable neoplastic disease. These agents are discussed in the order of their value to the clinician, as judged by their unique therapeutic activity and their general clinical effectiveness.

*Estrogens*

Estrogens are useful in the treatment of carcinoma of the prostate and, to a considerably lesser extent, in carcinoma of the breast. With the fundamental work of Huggins<sup>214</sup> in establishing the role of the steroid hormones in prostatic physiology, the therapeutic value of castration and estrogen therapy in carcinoma of the prostate was rapidly established.<sup>215</sup> Bilateral orchidectomy or estrogen therapy, in 50 to 75 per cent of patients with prostatic carcinoma, will produce rapid and remarkable effects—a decrease in the size of the enlarged prostate, degeneration of many of the neoplastic cells, a diminution in the size of metastases and recalcification of bone lesions, a fall in an elevated serum acid phosphatase level and a relief of pain, urinary-tract obstruction and disability. Hormonal therapy is not curative, however, and the patient ultimately becomes resistant to therapy, but life is often appreciably prolonged.<sup>216, 217</sup> This work has been reviewed by Nathanson.<sup>218</sup>

In the past two years the chief problem in estrogen therapy has been to establish the indications for its use in the proper management of prostatic carcinoma. Colston and Brendler<sup>219</sup> have recommended the use of stilbestrol, 1 to 2 mg daily, prior to radical prostatectomy. This procedure may possibly convert a localized but moderately advanced inoperable carcinoma into an operable one, and simplify the removal of an operable tumor. Herger and Sauer<sup>220</sup> believe that estrogen therapy is of no prophylactic value in slowly progressing, asymptomatic but inoperable carcinoma of the prostate, and they suggest that its early use may destroy the subsequent estrogen sensitivity of the disease. They have recommended that hormonal therapy be withheld until the disease is extensive or disabling symptoms are present. Deming<sup>221, 222</sup>

however, sanctions the use of estrogen therapy in all stages of inoperable prostatic carcinoma. It is generally agreed that since estrogens will produce therapeutic effects equal to castration, their use is to be preferred.<sup>217, 220-222</sup> When immediate relief is necessary, castration is indicated since its therapeutic effects appear within thirty-six hours, whereas estrogens require seven to ten days. Castration is also indicated in patients unable or disinclined to take estrogens, or in those who have relapsed under adequate estrogen therapy. It is not considered likely that castration will help the latter group, but the rare beneficial reports that have appeared seem to justify its trial.<sup>217, 220</sup> Conversely, in cases of castration relapse, estrogen therapy is sometimes effective.<sup>217</sup> There appears to be no good evidence of additive benefits from simultaneous therapy by castration and estrogens.

The estrogen preparations most frequently used are stilbestrol, 1 to 5 mg daily, and ethinyl estradiol, 0.1 to 0.5 mg daily. Dean<sup>217</sup> is of the opinion that ethinyl estradiol may be given in larger estrogen equivalent doses than stilbestrol, with less severe gastrointestinal symptoms. Other side effects of therapy are signs of feminization, particularly enlargement and tenderness of the breasts, and a decrease in libido.

The use of estrogens in the palliative treatment of mammary carcinoma is still in the experimental stage, but extensive clinical work is in progress.<sup>223-229</sup> Estrogens do not appear to be active<sup>227, 228</sup> against osseous metastases, which occur chiefly in the younger age groups, and they rarely exert a favorable effect on the disease in this group.<sup>224</sup> Indeed, there is evidence that estrogens sometimes accelerate the course of mammary cancer in young patients.<sup>227</sup> For these reasons, the use of estrogen therapy is entirely confined to postmenopausal patients, and it has been suggested that its use be restricted to women at least five years beyond the menopause.<sup>229</sup> In this group, 30 to 40 per cent of the patients have been found to show some temporarily favorable, but often only slight, response to therapy.<sup>224, 227</sup> This may consist of subjective improvement, regression of local tumors, shrinkage and healing of ulcers, reduction in the size and redness of skin metastases and decrease in the size of lymph-node and lung metastases. The usual

\*Associate, Sloan Kettering Institute for Cancer Research, fellow in medicine, Memorial Hospital Center for Cancer and Allied Diseases, fellow Jane Coffin Childs Memorial Fund for Medical Research.

dosage is 5 to 20 mg of stilbestrol daily.<sup>229</sup> These large doses may induce gastrointestinal disturbances, with nausea and vomiting, weight loss, diarrhea and uterine bleeding, edema and skin eruptions.

In mammary carcinoma in the male, estrogen therapy has not been tried extensively, but Nathanson<sup>226</sup> has recorded his impression that castration may be therapeutically more effective. Estrogens have been reported to produce tumor regressions in bladder papilloma and subjective improvement in bladder carcinoma.<sup>230</sup>

### *Nitrogen Mustard*

Gilman et al,<sup>231</sup> early in 1943, first reported, in a confidential military communication, on the clinical use of a nitrogen mustard compound, *tris* (beta-chloroethyl) amine hydrochloride in the treatment of neoplastic disease. Jacobson and his co-workers,<sup>232</sup> shortly afterward, began the clinical use of another nitrogen mustard, methyl-bis (beta-chloroethyl) amine hydrochloride, also known as DEMA or HN2, and this work was extended to two other clinics.<sup>233, 234</sup> Similar work was initiated in England by Wilkinson and Fletcher.<sup>235</sup> Because of military restrictions on the nitrogen mustards, none of the information could be reported until the end of World War II.<sup>114</sup> When these restrictions were lifted in 1946, an official statement was published<sup>236</sup> summarizing the clinical information available at that time, and distribution of the agent for clinical investigation was begun.<sup>237</sup> Since the inception of this study a number of clinical reports have appeared.<sup>238-250</sup>

HN2 must be given intravenously and, therefore, exerts its therapeutic action throughout the body. Recovery from the toxic effects of HN2 is more rapid than that from total body exposure to an equivalent effective dose of x-rays. This makes it possible to control HN2 dosage somewhat more closely than total body irradiation by x-rays or radioactive isotopes.

HN2 therapy has not proved to be a cure in any type of neoplastic disease, in leukemic mice, for example, four to ten times a lethal dose of HN2 *in vivo* is required to destroy the viability of the leukemic cells, a strain of cells considered to be unusually sensitive to HN2.<sup>28</sup> The rationale of HN2 therapy, therefore, consists in attempting to give the largest amount of HN2 consistent with doing no serious harm to the patient. The amount of HN2 that can be safely given varies considerably in different patients. Important factors in dosage are the patient's general condition, his hematologic status and his immediate prognosis—that is, greater risks can be taken if the immediate prognosis is poor.

The usual course of HN2 therapy consists of the intravenous injection of 0.1 mg per kilogram of body weight daily for four days, a total of 0.4 mg per kilogram. This is usually a safe dose, but in

some patients with depression of the hematopoietic system, especially that due to bone-marrow involvement with disease, or with very extensive, massive tumors, toxic effects may occur, and the drug should, therefore, be given more cautiously. A course of 0.4 mg per kilogram of body weight usually produces a moderate leukopenia, which develops gradually within seven to fourteen days, the white-cell count reaching a maximum of 1000 to 3000, followed by a relatively prompt recovery. There may be a mild depression in the platelet count, and usually the hemoglobin level is unaffected. The changes in the peripheral blood are paralleled in the bone marrow.<sup>238</sup> In selected cases the total course of HN2 may be given in two injections of 0.2 mg per kilogram of body weight or in a single dose of 0.4 mg per kilogram of body weight. If the usual total course of 0.4 mg of HN2 does not produce a satisfactory therapeutic result, and the peripheral-blood picture is relatively unchanged or has recovered, within two or three weeks, further HN2 may be given cautiously. In some patients, as a result of experience, it has been found that a total course of 1.0 mg per kilogram of body weight can be given safely in a three-week period—an amount of HN2 that would prove fatal in other patients.

If an excessive dose of HN2 is given, a characteristic toxicologic picture develops within seven to fourteen days, consisting of severe leukopenia, thrombocytopenia, with petechiae or purpura, a rapidly developing anemia, fever and weakness. The patient may bleed extensively from the nose, gums, kidneys and bowel, or into the skin, and even death may occur. Usually, however, recovery begins within four to ten days. Blood transfusions, as well as penicillin to ward off infections, appear to be the only agents of value in the treatment of this condition.

HN2 has two unpleasant incidental side effects. In many cases it produces thrombosis of the injected vein. This seems to occur more frequently when it is given by the direct syringe method than when injected into the tubing of a freely flowing intravenous infusion. Since the former method is simpler, it is more frequently used. If HN2 escapes from the vein it will produce an extensive local area of erythema, induration and eventually fibrosis. Within one to eight hours after an injection of HN2 most patients feel nauseated, and about 50 per cent vomit.<sup>234</sup> During the course of treatment, the patient may complain of weakness, anorexia and weight loss.

HN2 is not recommended for localized neoplastic disease, which can be treated more effectively with x-rays, with less discomfort to the patient and with longer clinical remissions. The agent has not been in use long enough to permit a definitive statement of its clinical value and the indications for its use.

but the available reports agree about its clinical effects

HN2 has found its most useful therapeutic role in the treatment of Hodgkin's disease<sup>232-233, 246, 247, 249</sup> It will induce a consistent clinical improvement in 80 to 90 per cent of treated patients The most striking effect is detoxification of the patient, with a prompt fall in fever increase in strength, appetite and weight Objectively, there may be a decrease in the size of enlarged lymph nodes, spleen and liver, clearing of pulmonary infiltrations and resorption of ascitic or pleural effusion Less consistently, there may be relief of bone pain or pruritus, shrinkage of involved, massively infiltrated tissues and recalcification of osseous lesions A remission may last from two weeks to more than a year, but the average duration is about six weeks The longer the remission from an adequate single course of therapy, the more favorable the outlook When the patient begins to relapse, another course of HN2 is usually indicated Some patients have received more than ten courses of treatment with repeated clinical responses, and with no definite evidence of cumulative damage to the bone marrow In most cases, however, the disease progresses, and the patient gradually becomes unresponsive to therapy

HN2 is suggested for the treatment of generalized Hodgkin's disease with systemic symptoms, and for use in patients believed to be "x-ray fast" A significant group of the "x-ray fast" patients may be salvaged for several months or longer by a course of mustard therapy This does not necessarily mean that the tissue in Hodgkin's disease unresponsive to x-rays can be affected by HN2, it probably does mean that the x-rays were not applied to the areas of active disease whereas a systemic form of therapy could ferret out these areas After satisfactory response of an "x-ray fast" patient to HN2 therapy, x-rays may then be used to treat localized disease There is no evidence that HN2, given early or late in Hodgkin's disease, alters the general course of the disease or prolongs life significantly It does, however, have an important and unique place in the management of the disease

HN2 has a definite palliative effect in mycosis fungoides<sup>244</sup> It will temporarily cause a regression of the skin lesions in patients no longer responding to or unsuitable for x-ray therapy The duration of remission to a course of treatment is variable, from only several days to six months or longer

Some patients with lymphosarcoma may respond to HN2 in a truly remarkable fashion, with rapid shrinkage of the enlarged lymph nodes, liver and spleen, and subjective improvement persisting for six months to a year or longer<sup>231-233, 235-237</sup> Another group with very aggressive disease may also show a marked but unsubstantial therapeutic response, relapsing within one or two weeks In

general, x-ray therapy is more satisfactory for the control of lymphosarcoma In some patients with extensive but relatively slowly progressive lymphosarcoma, HN2 may give remissions sufficiently long to make it a satisfactory alternative to x-ray therapy

Consistent clinical remissions can be induced in chronic myelogenous leukemia, with a fall in the white-cell count, a rise in hemoglobin level, a decrease in the size of an enlarged spleen and general improvement in the patient The remission usually continues for two or three months, and relapse is then fairly rapid Patients will continue to show some response to treatment until they reach the terminal stage Wintrobe et al<sup>238</sup> successfully maintained over many months 2 patients by periodic injections of HN2 There is little evidence that HN2 will prove effective in the treatment of patients unresponsive to adequate x-ray therapy In fact, in patients with very large spleens, greater relief is obtained from splenic irradiation than from systemic HN2 therapy

The results of HN2 therapy in chronic lymphatic leukemia have not been consistent These patients seem to have a greater tendency to develop a toxic reaction to HN2, which should therefore be given cautiously<sup>231</sup> Occasionally a patient may show a surprisingly good response, with a spontaneous rise in hemoglobin As Wintrobe<sup>238</sup> points out, however, patients in good condition usually show a good response to HN2, whereas those in poor condition, with generalized lymphadenopathy and anemia, do poorly

The acute leukemias do not show a satisfactory clinical response to HN2, although a fall in the white-cell count can be produced Relief of bone pain has been reported<sup>239</sup>

HN2 will induce a clinical remission in polycythemia vera<sup>17, 246</sup> similar to that produced by radioactive phosphorus It is too early to draw any conclusions regarding the consistency of this therapeutic effect, or the relative merits or hazards of HN2 therapy compared to other methods of treatment

In common with other agents, HN2 may cause some relief of pain in multiple myeloma, but there is no substantial evidence that the osseous lesions or the course of the disease is altered

HN2 has been found to produce transient symptomatic and occasional objective improvement in about 50 to 70 per cent of patients with inoperable carcinoma of the lung<sup>126, 241, 247</sup> These effects consist of relief of dyspnea and cough, decrease of sputum and hemoptysis and an increase in strength, appetite and weight The primary tumor and the metastases may show some decrease in size, and absorption of pleural effusions and aeration of atelectatic areas may occur There is occasionally relief of chest pain, and symptoms from obstruction of the superior vena cava may be markedly alleviated These therapeutic effects usually last

for from two weeks to two months only, and relapses develop rapidly. Patients with anaplastic carcinoma of the lung show a very dramatic symptomatic improvement, but they relapse quickly. Subsequent courses of treatment are usually not so successful, and HN2 therapy does not seem to cause a significant prolongation of life.

Circumscribed, inoperable carcinomas of the lung are best treated by x-rays. HN2 appears to be useful when the disease is extensive or severe symptoms are present. There does not appear to be any real evidence that its use in early carcinoma of the lung will significantly check the course of the disease.

In other types of carcinoma and sarcoma transient beneficial results have occasionally been reported, but these effects do not appear to be consistent. Further clinical investigation may disclose conditions in which HN2 will produce some consistent palliation.

Three general points about further indications for the use of HN2 may be considered, as follows:

HN2 does not seem to produce edema in tissues immediately following treatment, such as may occur after x-ray therapy. In obstructive tumors, such as lymphosarcoma pressing on the trachea, or obstruction of the superior vena cava from carcinoma of the lung, HN2 may be indicated prior to x-ray therapy.

Since the effects of HN2 are rapidly exerted it may be used as an emergency measure in selected cases. In patients in *extremis* from advanced but possibly responsive disease—and this situation has arisen chiefly in patients with lymphosarcoma or carcinoma of the lung—HN2 may produce remarkable improvement within twenty-four hours. Subsequently, a more considered program of therapy can then be started.

Studies are in progress to determine the value of combining the systemic effects of HN2 with localized x-ray therapy. In laboratory experiments, it has been shown that if HN2 is given before x-ray therapy an additive effect results, if given in the reverse sequence, x-rays seem to interfere with the action of HN2.<sup>28</sup> On the basis of these laboratory data, it seems reasonable, in the proper situation, to give HN2 prior to x-ray therapy.

### Radioactive Iodine

In 1940 Hamilton, Soley and Eichorn<sup>251</sup> demonstrated the selective deposition of radioactive iodine in human thyroid tissue, but only an insignificant amount was found in 2 carcinomas of thyroid origin studied. Metastatic thyroid carcinomas that selectively concentrate radioactive iodine were subsequently described.<sup>252, 253</sup> This concentration of radioiodine produces an intense and destructive local irradiation of thyroid tissue. Functional

thyroid tumors are rare, and it is estimated that only about 15 per cent of the tumors of thyroid origin will concentrate iodine.<sup>254</sup> In 19 selected thyroid tumors studied for their ability to take up radioactive iodine, 9 tumors, showing an orderly cell arrangement in a follicular pattern and containing colloid-like material, were capable of concentrating the iodine. These included 5 benign metastasizing strumas and 4 follicular adenocarcinomas. Of the remaining 10 solid alveolar or more anaplastic carcinomas, only 1 showed any evidence of iodine uptake.<sup>254</sup>

Thus far, only 1 patient has been reported in detail as having been treated successfully with radioactive iodine,<sup>255</sup> although additional reports are in press.<sup>256</sup> The selection of patients suitable for radioactive-iodine therapy is made by histologic examination of the tumor and by its ability to concentrate tracer doses of radioactive iodine. In patients with highly functional thyroid tumors, radioactive iodine will concentrate in the metastases. In most cases of functional thyroid tumors, however, the selective uptake of radioactive iodine is not great. The avidity of these tumors for radioactive iodine may be increased in some cases by surgical thyroidectomy, or "medical thyroidectomy" with radioactive iodine.<sup>257</sup> The radioactive iodine generally used is  $I^{131}$ , with a half-life of eight days. Large doses up to 200 millicuries have been given during a single course of treatment. The hazards of therapy are due to the radiation effects from radioactive iodine and the rapid destruction of active thyroid tissue.<sup>258</sup> In suitable cases, radioactive iodine will produce extraordinary tumor regressions and relief of pain and disability and will result in considerable prolongation of life. It is emphasized that patients must be carefully selected for treatment, and  $I^{131}$  administered with knowledge of the principles of thyroid physiology and radiation effects.

### Androgens

Androgenic substances have not been found to have such wide or specific applications as the estrogens in the treatment of cancer. Evidence is now accumulating that they have occasionally a temporary therapeutic effect on osseous metastases from carcinoma of the breast.<sup>256, 258, 265-267</sup> Although only a small number of cases have been reported in each series, certain preliminary generalizations appear justified. The preparation of androgen usually used is testosterone propionate. The premenopausal or younger patients with metastatic mammary carcinoma are considered most suitable for treatment. In about 50 per cent of the patients there will be some subjective improvement, with relief of pain and an increase in activity, appetite and a feeling of well-being. In 20 to 30 per cent of the patients with bone lesions, there will be x-ray evidence of regression and recalcification of the bone metastases. Less commonly, the primary

tumor or soft-tissue metastases will undergo regression<sup>225, 263</sup> If favorable clinical effects develop, they usually appear within two or three weeks of treatment and continue for variable but often short periods in the range of two to six months Under testosterone therapy the bone metastases may sometimes remain quiescent while the soft-tissue metastases progress Data are inadequate for discussion of the relative therapeutic merits of surgical or x-ray castration, alone or in combination with androgen therapy

A dosage schedule of 100 mg of testosterone propionate intramuscularly three times weekly has been suggested<sup>229</sup> This should be given for ten weeks and continued if improvement is satisfactory The side effects of testosterone administration — masculinizing effects, amenorrhea, edema and increased libido — should be taken into consideration in the decision to initiate therapy In patients with an elevated blood calcium level prior to treatment, testosterone therapy must be given with caution, since it may further raise the blood calcium to dangerous levels<sup>259</sup>

#### *Radioactive Phosphorus*

Radioactive phosphorus has been used clinically for almost ten years, and its therapeutic applications have been reviewed several times in the past three years<sup>8, 247, 264-270</sup> There is remarkable agreement concerning the place of this agent in the treatment of neoplastic disease It has not proved consistently useful in the treatment of Hodgkin's disease and lymphosarcoma, and it is without value in acute leukemia Its use is chiefly limited to certain disorders of the hematopoietic system

P<sup>32</sup> is considered by many to be the treatment of choice in polycythemia vera<sup>8, 247, 265, 266, 271, 272</sup> It will produce, almost invariably, marked symptomatic relief, a remission in the abnormal hematologic picture and a reduction in the size of an enlarged liver and spleen The usual duration of remission after an adequate single course of treatment is six to twelve months, but much longer remissions have occurred The serious complication of P<sup>32</sup> therapy is hematopoietic injury, with leukopenia, thrombocytopenia and anemia The usual dose is 4 to 7 millicuries intravenously, and further treatment may be given in one to three months if an adequate response has not been obtained The agent must be administered cautiously, since the maximum therapeutic and toxic effects usually do not appear before two weeks, and they may not reach maximum development for six months Furthermore, patients vary markedly in their sensitivity to P<sup>32</sup>, and an ineffective dose in one patient may be a toxic one in another There are some reservations about the use of P<sup>32</sup> in polycythemia vera Hall and Watkins<sup>266</sup> have suggested that the incidence of acute leukemia is higher in patients with polycythemia vera treated with P<sup>32</sup>, and Hahn<sup>177</sup> is of the opinion that P<sup>32</sup> is not necessarily

indicated in a disease that is treated so easily and effectively by other methods that have potentially less serious after effects

In chronic myelogenous leukemia, P<sup>32</sup> will induce typical clinical remissions, with a fall in white-cell count, rise in hemoglobin, reduction in the size of the spleen and symptomatic improvement The usual procedure is to administer P<sup>32</sup> cautiously, perhaps 1 to 2 millicuries twice a week until the white-cell count has begun to fall One patient may respond to a total dose of 5 millicuries, whereas another may need 25 millicuries When a clinical remission is induced, treatment is discontinued until relapse occurs<sup>265</sup> The nature and duration of remissions produced by P<sup>32</sup> are similar to those from x-rays, and, as with x-ray therapy, P<sup>32</sup> has only been found to produce a slight prolongation of life<sup>265</sup> Hall and Watkins<sup>266</sup> have raised the possibility that a greater number of cases of chronic myelogenous leukemia treated with P<sup>32</sup> terminate more frequently with acute leukemia than those treated by other means In chronic lymphatic leukemia P<sup>32</sup>, like other chemotherapeutic agents, does not produce clinical remissions as satisfactory or as consistently as in chronic myelogenous leukemia In many cases, however, a reduction in white-cell count, decrease in the size of enlarged nodes, liver and spleen, rise in hemoglobin and improvement in the general condition occur X-ray therapy is more effective in the treatment of large localized manifestations of lymphatic leukemia, but P<sup>32</sup> is of equal value in the therapy of generalized disease In multiple myeloma the drug has produced considerable relief of pain in 10 out of 14 patients in one series,<sup>266</sup> but it has not affected tumor growth or altered the progressive course of the disease

It is apparent that P<sup>32</sup> is neither unique nor irreplaceable in the treatment of neoplastic diseases of the hematopoietic system Its fourteen-day half-life sometimes makes the tissue radiation dosage difficult to regulate, and other radioactive isotopes may prove more satisfactory in certain cases

#### *Urethane*

Urethane was first tried clinically by Paterson et al<sup>146</sup> in the treatment of miscellaneous tumors, including carcinoma of the breast, but the results indicated only slight or inconstant chemotherapeutic activity Since some of these patients developed leukopenia, the drug was given to patients with chronic myelogenous and lymphatic leukemia and, in these diseases, characteristic temporary clinical remissions were obtained

Urethane is a drug of low toxicity, and in the past it has been used as a hypnotic The dose usually recommended for the treatment of leukemia is 2 to 4 gm daily for two to six weeks or until a therapeutic effect results It may be given orally<sup>146</sup> in an aqueous solution, by enteric coated capsules or parenterally<sup>273</sup> Nausea and occasionally vomit-

ing are complications of treatment, but this is rarely sufficiently severe to necessitate cessation of treatment. Larger doses up to 15 gm a day have been given.<sup>27</sup> The large doses have a hypnotic and moderately intoxicating effect. The results of excessive urethane therapy have not been definitely established, but the drug should be administered cautiously and the hematologic picture carefully followed. In patients with leukemia there is no doubt that urethane will produce a severe depression of the bone marrow.<sup>146, 273</sup> It seems likely that patients with normal bone marrow exposed continuously to large doses of urethane will show hematopoietic injury, with leukopenia, anemia, thrombocytopenia and bleeding. Moeschlin,<sup>148</sup> however, has been unable to produce any injury to the bone marrow of normal male patients by the continuous administration of urethane. Urethane has a moderately cumulative effect, and its hematologic action in leukemia varies with the total amount and the daily dosage of the drug administered. No evidence has been presented that urethane induces pulmonary adenomas in man, although this possibility must be considered.

Since the initial publication on the clinical effects of urethane in leukemia, several confirmatory reports have appeared.<sup>273-276</sup> The most successful results have been obtained in chronic myelogenous leukemia. Within one to three weeks after urethane treatment was begun, there was, in almost all cases, a fall in the white-cell count, a tendency of the differential to return toward normal, a rise in the hemoglobin and a reduction in the size of the spleen. The total dose required to accomplish this ranged from 19 to 325 gm, and remissions usually occurred within ten to thirty-one days. Patients relapse under treatment, however, and there is no evidence that life is appreciably prolonged or the course of the disease altered by the treatment. Patients in the terminal stage of chronic myelogenous leukemia do not respond well to urethane. In chronic lymphatic leukemia the results in general have not been so satisfactory as those in myelogenous leukemia, although in the majority of cases treated, a temporary remission of the disease has been induced, with regression in the size of diseased organs, a rise in hemoglobin level, a decrease in the white-cell count and an absolute increase in the polymorphonuclear leukocytes. In Paterson's<sup>274</sup> series 13 out of 23 patients showed improvement, 5 were unaffected, and 5 became worse. In a smaller series of 8 cases, Hirschboeck et al.<sup>275</sup> observed a satisfactory remission in 3 cases, a fair result in 2 and poor results in the remainder. No significant clinical improvement has been observed in acute leukemia, although the white-cell count may be lowered. There have been no consistent results from the use of the drug in lymphosarcoma or Hodgkin's disease.<sup>146, 276</sup> A remarkable remission in an anaplastic carcinoma metastatic to the skin has been reported.<sup>277</sup> In 4 patients with prostatic

carcinoma no longer responding to hormonal control, large doses of urethane caused some shrinkage of the primary tumor, a decrease in acid phosphatase, a relief of pain and a sense of well-being.<sup>278</sup> One of these patients died of hepatic necrosis, which could not definitely be attributed to the urethane therapy.

In general, in the treatment of chronic myelogenous and lymphatic leukemia, urethane can be expected to produce remissions similar to those effected by x-ray therapy, radioactive phosphorus, nitrogen mustard and Fowler's solution.<sup>276</sup> Its action is perhaps not so consistent, precise and predictable as that of the more toxic agents, and it is unlikely that urethane will be effective in patients in whom these other agents fail. Furthermore, at effective doses, it has a toxic effect on the bone marrow and should, therefore, be administered cautiously.

#### *Fowler's Solution*

Although there are no recent papers on the use of potassium arsenite in leukemia, it is well established as a useful agent for inducing clinical remissions in early and responsive cases of chronic myelogenous and lymphatic leukemia.<sup>279</sup>

\* \* \*

Only a small group of human neoplastic diseases is susceptible to the palliative effects of chemotherapeutic agents. In carcinoma of the prostate estrogens may temporarily halt the disease and prolong life, in an occasional patient with carcinoma of the thyroid gland radioactive iodine is effective in interrupting the disease and prolonging life, in Hodgkin's disease nitrogen mustard serves as a useful adjuvant to x-ray therapy, and this appears to be true, but to a lesser extent, in lymphosarcoma and mycosis fungoides, in chronic myelogenous and chronic lymphatic leukemia. Fowler's solution, urethane, nitrogen mustard and radioactive phosphorus are all capable of inducing clinical remissions when the patient is responsive to therapy, but they are all uniformly less effective when the patient approaches the terminal or acute stage, in polycythemia vera radioactive phosphorus and, possibly to a lesser extent, nitrogen mustard will induce excellent clinical remissions, in carcinoma of the lung nitrogen mustard may produce transient palliative effect, and in mammary carcinoma in postmenopausal patients estrogen therapy may produce temporary palliation and tumor regressions—in the premenopausal patient with osseous metastases androgens are more effective. Inconstant and unpredictable transient responses to some of these chemotherapeutic substances have been reported in a variety of other tumors.

It is to be hoped that in future reviews the great efforts of the laboratories and clinics in cancer therapy will result in a longer list of neoplastic diseases responsive to more effective chemotherapeutic agents.

### CASE 34341

#### PRESENTATION OF CASE

A forty-eight-year-old hide merchant was admitted to the hospital because of abdominal pain.

The patient developed vague, epigastric discomfort and nausea approximately forty-eight hours previous to admission following the ingestion of food. This subsided soon but recurred each time he ate. Three hours before admission the pain became severe, cramping and localized in the mid-abdomen, and was accompanied by vomiting. At times borborygmus was audible to the patient.

Approximately one year before admission an appendectomy was performed at another hospital. It was said to be a difficult operation and there was a question of the appendix having ruptured. An abscess of the abdominal wall complicated his convalescence. Three months after this the patient began having difficult bowel movements with occasional diarrhea and intermittent lower abdominal pain. A physician at this time noted a firm, tender mass in the right lower quadrant. The stools were not bloody or tarry. For several months before admission the patient had intermittent chills and fever. X-ray studies of the entire gastrointestinal tract six months before entry were reported to be negative. Three and a half years previous to admission the patient had a coronary occlusion. While convalescing from this he had one episode of hematemesis and repeated tarry stools presumed to be due to a peptic ulcer.

Physical examination revealed a pale man in no acute distress. The heart and lungs were normal. The abdomen was tympanitic. In the right lower quadrant a mass extended from beneath the appendectomy scar toward the pubis. It was 8 to 10 cm in diameter, firm, fixed and somewhat tender. There was also diffuse tenderness in the epigastrium. Peristaltic sounds were high-pitched. Bilateral, easily reduced inguinal hernias were present.

The temperature, pulse and respirations were normal. The blood pressure was 125 systolic, 75 diastolic.

The urine had a specific gravity of 1.026 and gave a ++ test for albumin, and the sediment contained frequent hyaline casts and 4 pus cells per high-power field. Examination of the blood disclosed a hemoglobin of 15.5 gm and a white-cell count of 15,100, with 90 per cent neutrophils. A stool specimen was guaiac negative. An electrocardiogram was suggestive of an old posterior myocardial infarct. An x-ray film of the abdomen showed gas scattered throughout the large bowel, and there appeared to be two dilated loops of small bowel in the midabdomen.

The patient was given fluids intravenously, and a Miller-Abbott tube was passed.

An operation was performed on the second hospital day.

#### DIFFERENTIAL DIAGNOSIS

DR HENRY H FAXON Shall we review the x-ray films, Dr Wyman?

DR STANLEY M WYMAN The loops of dilated bowel, apparently small bowel, are seen in the left middle and lower abdomen. I cannot see the gas described in the colon. There is a large collection of gas in the right upper abdomen, the location of which I cannot determine. This shadow may represent ileum but is probably colon, at least there are very few haustral markings. The stomach is seen in the upper midabdomen. There is an absence of any great degree of gas in the right lower abdomen, but there are a number of small collections of gas, the locus of which is not certain, and the appearance is quite atypical. The film taken the next day again shows several loops of gas-containing small bowel that do not appear so widely dilated as those at the last observation. Here again there are small collections of gas in the right lower abdomen in a rather atypical pattern.

DR FAXON Could this gas be free in the peritoneal cavity?

DR WYMAN I do not believe so.

DR FAXON Could the strange patches of gas that you speak of be in the subcutaneous tissue?

DR WYMAN They suggest gas outside the bowel somewhere, and they are quite consistent with what is seen in abscess.

DR FAXON Is there any gas in the rectum?

DR WYMAN No.

DR FAXON Can you see the kidney shadows?

DR WYMAN The left kidney shadow is quite well outlined, the right is less well outlined. Both are normal in size, shape and position.

DR FAXON The case falls into two separate parts: the nature of this chronic mass in the right lower quadrant and the acute episode that precipitated the hospital entry. Apparently, the mass appeared approximately nine months before entry, for he was operated on one year before entry and it was three months later that his doctor discovered a mass in the right lower quadrant. It is rather

surprising that more intensive studies had not been done to determine the correct diagnosis in the intervening months. So far as the mass in the right lower quadrant is concerned, it seems to me that we have to consider two main classifications—a tumor or an inflammatory mass. If a tumor, it may have been of the bowel or retroperitoneal space. In favor of its being a tumor is its long persistence with relatively little change. The age and general appearance of the patient are consistent with a malignant lesion of the right colon or of the bowel, and the law of averages favors its being a neoplasm. I mention this because I think that the burden of proof lies on the person who says that this was not a growth of some kind. Did he have a barium enema?

DR WYMAN: No.

DR FAXON: When one is in doubt a barium enema carries with it little risk and often gives much helpful information. The mass, from the description, seems to be fairly anterior and not to lie deep in the pelvis. X-ray studies should have been repeated even if they were negative six months before. It is notorious and readily admitted that the right colon is the portion of the gastrointestinal tract in which it is especially hard to visualize a malignant growth by x-ray study. The fact that six months before entry the mass was present and the roentgenologists were unable to say if it was an intrinsic lesion of the bowel does not rule out the possibility of its being inherent in the intestine but makes such localization of the lesion most unlikely.

There are a few points against the diagnosis of a malignant growth. In the first place if it had been of the bowel and possibly missed by the earlier x-ray examination, the patient should have shown anemia. Right-sided lesions are notorious for the anemia that they cause. But here we have a case in which examination of the stool was negative and the hemoglobin was 15.5 gm, although this may be accounted for in part by dehydration. We are not told how much he vomited.

The second argument against neoplasm is that within three months after the previous operation a mass was felt for the first time and had grown to a size that was easily palpable by the patient's physician. The description of the difficulties encountered by the surgeon suggest that the first operation very obviously might have been misdirected, and although he took the appendix out it is possible that the essential disease was neither dealt with nor recognized.

It could, of course, have been a retroperitoneal lymphoma, but again I think it is unlikely that the patient would have remained in such apparently good condition over such a long period.

In considering the second possibility, that the mass in the right lower quadrant was inflammatory, it should be pointed out that the symptoms

started as those of irritation of the lower bowel, with diarrhea and difficult bowel movements. The diarrhea and intermittent lower abdominal pain could have been caused by extrinsic pressure or infection on the lower bowel. This antecedent inflammatory process for which the patient had been operated upon would have given cause for the subsequent development of an inflammatory area in the right lower quadrant. We know that pus had been present in a sinus and that the wound had become infected and drained for a considerable period. It is interesting that the wound eventually healed, which would be unlikely with tuberculosis, actinomycosis or a spreading type of infection. He had chills and fever for several months, which again suggest an inflammatory process. The temperature was normal at the time of admission here, but I do not believe that would change our premise that this was an inflammatory mass, which had been present so long and was so completely walled off that he might have evinced his hyperthermia earlier and reached the stage where he had little or no fever. He had an elevated white-cell count, and of even more significance is the fact that the smear showed 90 per cent neutrophils. There is therefore much to suggest that this was an inflammatory lesion. The absence of blood in the stools is consistent with a mass outside the bowel, which I am postulating may well have been inflammatory. However, if it was an inflammatory process of the usual variety, it should not have persisted this long unless either some recurrent cause for the infection existed or a very unusual type of infection such as tuberculosis, actinomycosis, regional ileitis or diverticulitis was present. A foreign body might have been keeping the inflammation going. The patient was rather old for regional ileitis, and although diverticulitis often gives this type of picture it is in the left lower rather than the right lower quadrant. Meckel's diverticulum has little to recommend it as a diagnosis. Volvulus or intussusception would not have lasted this long. A foreign body, left at the previous operation, could quite readily have caused an inflammatory mass of this nature. A fecalith from the ruptured appendix might have persisted for a long time and would have kept an inflammatory reaction going.

I do not believe the mass on the right side was kidney, it seemed too low, and there was not enough wrong with the genitourinary tract to make it seem likely that that was the cause of the lesion. I do not believe the gastric ulcer three years previously was more than an incidental finding of the past, nor do I think that the inguinal hernia or the coronary disease had anything to do with the picture.

Regarding the symptoms that brought him into the hospital, I think that they were typical of small-bowel obstruction, in which there is either a paralytic, inflammatory type of obstruction, such as

An x-ray film of the abdomen showed gas scattered throughout the large bowel, and there appeared to be two dilated loops of small bowel in the midabdomen.

The patient was given fluids intravenously, and a Miller-Abbott tube was passed.

An operation was performed on the second hospital day.

#### DIFFERENTIAL DIAGNOSIS

DR. HENRY H. FAXON: Shall we review the x-ray films, Dr. Wyman?

DR. STANLEY M. WYMAN: The loops of dilated bowel, apparently small bowel, are seen in the left middle and lower abdomen. I cannot see the gas described in the colon. There is a large collection of gas in the right upper abdomen, the location of which I cannot determine. This shadow may represent ileum but is probably colon; at least there are very few haustral markings. The stomach is seen in the upper midabdomen. There is an absence of any great degree of gas in the right lower abdomen, but there are a number of small collections of gas, the locus of which is not certain, and the appearance is quite atypical. The film taken the next day again shows several loops of gas-containing small bowel that do not appear so widely dilated as those at the last observation. Here again there are small collections of gas in the right lower abdomen in a rather atypical pattern.

DR. FAXON: Could this gas be free in the peritoneal cavity?

DR. WYMAN: I do not believe so.

DR. FAXON: Could the strange patches of gas that you speak of be in the subcutaneous tissue?

DR. WYMAN: They suggest gas outside the bowel somewhere, and they are quite consistent with what is seen in abscess.

DR. FAXON: Is there any gas in the rectum?

DR. WYMAN: No.

DR. FAXON: Can you see the kidney shadows?

DR. WYMAN: The left kidney shadow is quite well outlined, the right is less well outlined. Both are normal in size, shape and position.

DR. FAXON: The case falls into two separate parts: the nature of this chronic mass in the right lower quadrant and the acute episode that precipitated the hospital entry. Apparently, the mass appeared approximately nine months before entry, for he was operated on one year before entry and it was three months later that his doctor discovered a mass in the right lower quadrant. It is rather

surprising that more intensive studies had not been done to determine the correct diagnosis in the intervening months. So far as the mass in the right lower quadrant is concerned, it seems to me that we have to consider two main classifications—a tumor or an inflammatory mass. If a tumor, it may have been of the bowel or retroperitoneal space. In favor of its being a tumor is its long persistence with relatively little change. The age and general appearance of the patient are consistent with a malignant lesion of the right colon or of the bowel, and the law of averages favors its being a neoplasm. I mention this because I think that the burden of proof lies on the person who says that this was not a growth of some kind. Did he have a barium enema?

DR WYMAN: No.

DR FAXON: When one is in doubt a barium enema carries with it little risk and often gives much helpful information. The mass, from the description, seems to be fairly anterior and not to lie deep in the pelvis. X-ray studies should have been repeated even if they were negative six months before. It is notorious and readily admitted that the right colon is the portion of the gastrointestinal tract in which it is especially hard to visualize a malignant growth by x-ray study. The fact that six months before entry the mass was present and the roentgenologists were unable to say if it was an intrinsic lesion of the bowel does not rule out the possibility of its being inherent in the intestine but makes such localization of the lesion most unlikely.

There are a few points against the diagnosis of a malignant growth. In the first place if it had been of the bowel and possibly missed by the earlier x-ray examination, the patient should have shown anemia. Right-sided lesions are notorious for the anemia that they cause. But here we have a case in which examination of the stool was negative and the hemoglobin was 15.5 gm, although this may be accounted for in part by dehydration. We are not told how much he vomited.

The second argument against neoplasm is that within three months after the previous operation a mass was felt for the first time and had grown to a size that was easily palpable by the patient's physician. The description of the difficulties encountered by the surgeon suggest that the first operation very obviously might have been misdirected, and although he took the appendix out it is possible that the essential disease was neither dealt with nor recognized.

It could, of course, have been a retroperitoneal lymphoma, but again I think it is unlikely that the patient would have remained in such apparently good condition over such a long period.

In considering the second possibility, that the mass in the right lower quadrant was inflammatory, it should be pointed out that the symptoms

started as those of irritation of the lower bowel, with diarrhea and difficult bowel movements. The diarrhea and intermittent lower abdominal pain could have been caused by extrinsic pressure or infection on the lower bowel. This antecedent inflammatory process for which the patient had been operated upon would have given cause for the subsequent development of an inflammatory area in the right lower quadrant. We know that pus had been present in a sinus and that the wound had become infected and drained for a considerable period. It is interesting that the wound eventually healed which would be unlikely with tuberculosis, actinomycosis or a spreading type of infection. He had chills and fever for several months, which again suggest an inflammatory process. The temperature was normal at the time of admission here but I do not believe that would change our premise that this was an inflammatory mass, which had been present so long and was so completely walled off that he might have evinced his hyperthermia earlier and reached the stage where he had little or no fever. He had an elevated white-cell count, and of even more significance is the fact that the smear showed 90 per cent neutrophils. There is therefore much to suggest that this was an inflammatory lesion. The absence of blood in the stools is consistent with a mass outside the bowel, which I am postulating may well have been inflammatory. However, if it was an inflammatory process of the usual variety, it should not have persisted this long unless either some recurrent cause for the infection existed or a very unusual type of infection such as tuberculosis, actinomycosis, regional ileitis or diverticulitis was present. A foreign body might have been keeping the inflammation going. The patient was rather old for regional ileitis, and although diverticulitis often gives this type of picture it is in the left lower rather than the right lower quadrant. Meckel's diverticulum has little to recommend it as a diagnosis. Volvulus or intussusception would not have lasted this long. A foreign body, left at the previous operation, could quite readily have caused an inflammatory mass of this nature. A fecalith from the ruptured appendix might have persisted for a long time and would have kept an inflammatory reaction going.

I do not believe the mass on the right side was kidney, it seemed too low, and there was not enough wrong with the genitourinary tract to make it seem likely that that was the cause of the lesion. I do not believe the gastric ulcer three years previously was more than an incidental finding of the past, nor do I think that the inguinal hernia or the coronary disease had anything to do with the picture.

Regarding the symptoms that brought him into the hospital, I think that they were typical of small-bowel obstruction, in which there is either a paralytic, inflammatory type of obstruction, such as

occurs in general peritonitis following ruptured appendix, or a mechanical obstruction. This man had plenty of reason for mechanical obstruction, both by the mass that was present, which might have involved the small intestine, and from the previous peritonitis, which might have left bands that could cause kinking. If this obstruction had been on a paralytic basis, the patient should have been sicker than he was and should have had absent peristalsis, and the abdomen should have been rigid. Furthermore, there should have been some good etiology such as a perforated ulcer, which I think in this case is highly unlikely. I do not believe that he fits the picture of a dynamic ileus. On the other hand, with mechanical obstruction of the small bowel, a patient is not of necessity especially ill until obstruction has gone on for such a long time that there is increased high-pitched peristalsis, persistent vomiting and dilated loops of small bowel by x-ray examination. Although it is tempting to say that this man had small-bowel obstruction, secondary to a neoplasm or a growth of some kind, I shall put down as my diagnosis mechanical small-bowel obstruction secondary to an inflammatory mass in the right lower quadrant caused by and persisting because of a foreign body retained at the first operation.

#### CLINICAL DIAGNOSIS

Inflammatory lesion, region of cecum, due to regional enteritis or foreign body

#### DR FAXON'S DIAGNOSIS

Small-bowel obstruction due to inflammatory mass caused by foreign body

#### ANATOMICAL DIAGNOSES

*Carcinoma of stomach, with peritoneal metastases*  
*Small-bowel obstruction*

#### PATHOLOGICAL DISCUSSION

DR TRACY B MALLORY Dr Claude Welch, who operated on this patient, is operating and unable to get here. He called me on the telephone, however, just before the conference and asked me to say that his preoperative diagnosis was an inflammatory lesion in the region of the cecum due (first choice) to regional enteritis or (second choice) to a retained foreign body. He was forced to operate on the patient without complete study because of the inability to control the intestinal obstruction in any other way.

At operation he found a mass in the region of the cecum, which appeared to be granulomatous and inflammatory. There were also, however, some nodules seen on the peritoneal surface elsewhere. When he explored further he found a large tumor mass in the pyloric portion of the stomach, occupying most of the lesser curvature. He felt reasonably sure from palpation that it was a neo-

plastic lesion in the stomach. He was still inclined to think that the lesion in the region of the cecum was inflammatory. He took a biopsy from that and also from one of the peritoneal nodules, and both showed metastatic carcinoma. He relieved the intestinal obstruction by doing a side-to-side anastomosis between the ileum and the sigmoid, since the lumen of the entire ascending colon was compromised by a mass, whatever it was. Subsequent x-ray examination of the stomach was done. That showed a fairly characteristic picture. Dr Wyman will show the films.

DR WYMAN The film demonstrates fairly well an annular carcinoma involving the distal third of the stomach.

DR FAXON Do you suspect that the bleeding of three years previously was related to the lesion found in the stomach at the time of operation?

DR MALLORY Probably.

Dr Welch has just arrived. We have just finished discussing your case, and Dr Faxon's diagnosis was an inflammatory lesion of the cecum, probably secondary to retained foreign body.

DR CLAUDE E WELCH I am sorry that I missed his discussion. I think that I might answer any questions that may have been raised by the brief summary of a quite confusing case. The things that impressed us before operation were the inflammatory mass in the right lower quadrant and the signs of intestinal obstruction, the history of which was rather chronic. We thought the best way to put the whole story together was on the basis of regional enteritis that had perforated, forming an abscess, first intraperitoneally and then perforating into the abdominal wall. We were not very happy about the diagnosis, but we had to operate on him on that basis.

DR FAXON Have you seen many cases of regional enteritis in this age group?

DR MALLORY It usually occurs in the twenties, although we do see it occasionally in older patients.

DR FAXON As a matter of curiosity, were the x-ray films of the gastrointestinal tract taken six months prior to operation reviewed?

DR WYMAN They have been since, and they appeared to be entirely normal.

#### CASE 34342

#### PRESENTATION OF CASE

A forty-six-year-old man entered the hospital because of hematuria.

The present illness began five weeks before admission with anorexia, nausea and occasional vomiting. At the same time he noted some red spots on his skin. These came and went and were slightly itchy but never tender. Four weeks before admission the urine was noted to be pink, and this sign also fluctuated in degree during the succeeding

period Three weeks before admission the family physician discovered albumin and red cells in the urine No history of other abnormal bleeding could be elicited, and there were no other urinary symptoms There had been some ulcer-like abdominal pain in the past, but this was not a part of the present illness nor were there any chills, fever or severe malaise

The past history disclosed rheumatoid arthritis, which had bothered the patient for eight years prior to admission but had never caused any severe pain or disability Three years before admission a diagnosis of pulmonary tuberculosis was made The disease was treated by thoracoplasty and considered quiescent one year later There was no history of rheumatic fever, scarlet fever or kidney disorders

Physical examination showed a well developed and well nourished man sitting up in bed On the skin there were purplish, nonblanching spots in small clusters and larger ecchymotic spots chiefly over the lower legs The mucous membranes and nailbeds were clear The thoracoplasty wound on the left side was well healed The breath sounds were slightly depressed on the right, but no rales or areas of dullness were made out The heart was normal except for a Grade II basal systolic murmur heard best along the left sternal border The liver edge was felt slightly below the costal margin, otherwise examination of the abdomen was negative Rectal examination was also negative The hands and feet showed slight rheumatoid changes

The temperature, pulse and respirations were within normal limits The blood pressure was 120 systolic, 75 diastolic

Examination of the blood disclosed a hemoglobin of 9.4 gm and a white-cell count of 13,500, with 84 per cent neutrophils The urine showed a specific gravity of 1.008, gave a +++ test for albumin, and the sediment was "loaded" with red cells A stool specimen was guaiac negative Culture of the sputum grew a rare beta-hemolytic streptococcus and abundant colonies of *Neisseria catarrhalis*, a concentration was negative for acid-fast bacilli Culture of the urine grew a few colonies of *Staphylococcus albus* The sedimentation rate was slightly elevated A tourniquet test was negative The nonprotein nitrogen was 136 mg, and the total protein 6.1 gm per 100 cc, with an albumin-globulin ratio of 1.78 The carbon dioxide was 21.3 and the chloride 84 milliequiv per liter The prothrombin time was 20 seconds (normal, 17 seconds) A congo-red test was unsatisfactory X-ray examination of the chest showed the thoracoplasty on the left, fibrosis with emphysematous blebs throughout both lungs and a soft mottling at the left hilus extending inferiorly Retrograde pyelograms showed a faint, irregular calcification overlying the upper third of the left kidney just

above the middle calyx, and constant beading of the ureters

In the hospital the patient's symptoms continued unchanged, and he developed hemoptysis, which gradually increased in severity until considerable respiratory difficulty was produced and clots were raised On auscultation of the lungs numerous rhonchi and moist medium rales were heard throughout, and a chest plate showed extensive mottling in both lung fields On the ninth hospital day his condition deteriorated rapidly, the pulse and respirations rising although the blood pressure remained stable and the temperature was normal He died the same day

#### DIFFERENTIAL DIAGNOSIS

DR REED HARWOOD Let us look at the x-ray films

DR STANLEY M WYMAN This is the old left thoracoplasty involving the upper ribs, and marked collapse of the upper half of the lung field is well demonstrated The diaphragm is low in position, being at the level of the twelfth rib There is fibrosis throughout both lung fields, most marked in the upper portion of the right There is probably a small quantity of fluid or possibly thickened pleura at the right base, and a fine, indefinite mottling in both lung fields, which may represent edema The heart shadow itself is not remarkable The film taken five days later shows this extensive, very pronounced change with a heavy, granular density throughout the central portions of both lung fields, sparing only the bases and the portion under the thoracoplasty The area of calcification in the left kidney is fairly well demonstrated The lesion in this area when injected with dye is seen to be present in the middle and upper calyces The remaining calyces are normal in appearance, and the beading of the ureter is well seen The spleen appears to lie unusually low and is probably enlarged The liver also extends well down and is also probably enlarged The right-kidney calyces and pelvis appear normal, but there are two or three small areas suggesting beading in the ureter

DR HARWOOD Is this picture typical of the kind of pulmonary edema that one often sees in uremia?

DR WYMAN Yes, it appears to be quite consistent

DR HARWOOD What is the significance of the beading of the ureter?

DR WYMAN It is usually thought to mean old infection, such as tuberculosis In keeping with that is the calcification apparently in the kidney parenchyma

DR HARWOOD We are faced with the problem of making a diagnosis of what type of renal disease this patient had What combination will commonly give nitrogen retention and hematuria? Cancer we can satisfactorily exclude Amyloid disease was thought of in this case but I believe

that hematuria is an unusual manifestation of amyloid disease. Prostatic hypertrophy and obstruction can produce hematuria and uremia, but there is no evidence of difficulty in urination in this case and no difficulty in passing the cystoscope. I think that that can be excluded. It is said that at least 10 per cent of patients with pulmonary tuberculosis have lesions in the kidney of greater or less severity. We cannot exclude the presence of tuberculosis in this patient. Indeed, I think it likely that he did have a tuberculous lesion of the left kidney. Hematuria, of course, is a common symptom of this disease, but there is another characteristic of renal tuberculosis—namely, that despite considerable destruction of the renal parenchyma, renal failure is rare. Furthermore, most cases of advanced renal tuberculosis also have tuberculosis in the bladder, which can be readily excluded by cystoscopy in this case, and by the lack of symptoms of cystitis. Pyelonephritis is another condition in which hematuria and albuminuria and nitrogen retention are found. It is distinctly unusual, though, to have blood alone without pus in the urine and very unusual not to have fever and cystitis. I therefore think that pyelonephritis is unlikely. Glomerulonephritis is next to be considered. Of course glomerulonephritis will produce hematuria and nitrogen retention. Casts are also commonly found in glomerulonephritis, but they are not mentioned in the record of the case under discussion. Hypertension, generalized edema and retinal hemorrhages were absent in this case. I do not believe that we can exclude the possibility of glomerulonephritis with terminal uremia, but it is unlikely.

The skin lesions may be an important clue. They suggest to me the possibility of two diseases: Henoch's purpura and periarteritis nodosa. A recent review of Henoch's purpura by Gairdner\* tells us that joint and skin lesions are the commonest manifestations of Henoch's purpura. Most cases also show evidence of renal involvement, and some patients die in renal failure. It is significant that the cases reported all show macroscopic hematuria. The condition usually occurs in young people, although cases have been reported in later life, and it is more common in males than females. Death from renal failure is not uncommon, and it is of interest that the autopsy reports show "glomerular nephritis." The negative tourniquet test in this patient does not exclude the diagnosis of purpura because sometimes the tourniquet test is positive. Possibly against the diagnosis of Henoch's purpura is the total absence of lesions of the gastrointestinal tract. Cases have been reported, however, in which only renal disturbance has been noted.

Periarteritis nodosa can involve any arteries in the body, and it is perfectly possible that the vessels of the kidney and skin were involved in periarteritis nodosa in this case. The absence of eosinophilia is possibly against this diagnosis. I have the feeling that this patient died of a generalized vascular disturbance. As Gairdner points out, the three conditions under discussion—purpura, periarteritis and nephritis—are closely allied in some respects, both pathologically and possibly etiologically. In my diagnosis I place Henoch's purpura as my first choice, periarteritis nodosa as my second, and acute glomerulonephritis as my third.

DR ALFRED KRANES: Are you able to make a diagnosis of Henoch's purpura anatomically?

DR TRACY B. MALLORY: I do not know how to.

DR DONALD S. KING: Would you get that much hemoptysis from pulmonary edema, Dr Harwood?

DR HARWOOD: How much was there?

DR KING: The patient raised clots.

DR JACOB LERMAN: One occasionally sees that much in rheumatic heart disease, but there is no evidence of that here.

DR KING: That is right, but this man had no mitral stenosis. Does hemoptysis occur in purpura?

DR HARWOOD: It must be distinctly unusual. I could find no mention of it in the literature.

DR KING: I cannot remember having seen any. I would almost have to get an infarct into this case to explain the hemoptysis.

DR HARWOOD: I would not go any farther than to say that it was a terminal event.

DR KING: Most of the cases here are that.

DR HARWOOD: I mean that the patient did not die from the hemoptysis.

DR PAUL C. ZAMECNIK: I think it is interesting that the purpura seemed to follow the scratch marks and that the purpuric spots did not fade very quickly. I saw them one day and about two days later they had not changed. The patient seemed to run a strikingly rapid downhill course. He was admitted on the genitourinary service with a question of renal stone. Once that was ruled out he was transferred to the medical service. It is interesting that at the time I saw him the non-protein nitrogen was 100 mg per 100 cc. He was relatively symptom free, and four days later he died. We had the feeling that we were missing something all along, but all we could put our finger on was the renal damage. In the absence of anything else we said it was acute or subacute glomerulonephritis.

DR LERMAN: In the presence of tuberculosis, as this kidney suggests, amyloid disease is always a good bet.

DR HARWOOD: He may have had some, but do you believe that he died from it?

DR LERMAN: No, he might have bled from the tuberculous focus in the lung.

\*Gairdner, D. Schönlein-Henoch syndrome (anaphylactoid purpura). *Quart J Med* 17:95-122, 1948.

DR KING That is what I was wondering about. Old tuberculous lesions with thoracoplasty bleed. However, we have no evidence for it.

DR MALLORY It was strongly considered on the wards to account for the hemoptysis.

#### CLINICAL DIAGNOSES

Pulmonary tuberculosis, with hemorrhage  
Subacute glomerulonephritis

#### DR HARWOOD'S DIAGNOSES

Henoch's purpura  
Periarteritis nodosa?  
Acute glomerulonephritis?  
Uremia  
Pulmonary edema

#### ANATOMICAL DIAGNOSES

*Subacute glomerulonephritis*  
*Pulmonary edema, with massive hemorrhage into lungs*  
*Purpura*  
Pulmonary tuberculosis, healed  
Operation thoracoplasty, left

#### PATHOLOGICAL DISCUSSION

DR MALLORY The striking lesion found at autopsy was in the kidneys. They were considerably enlarged, weighing 510 gm, with a grayish yellow cortex and peppered over with small red spots — a typical picture for subacute glomerulonephritis. That was confirmed microscopically. The only other findings of great interest at autopsy were in the lungs, and they were somewhat difficult to interpret.

The tuberculosis was on the whole very well healed. We found only two or three quite small lesions that showed any degree of activity, but none of them we felt could be responsible for the hemorrhage. On the other hand, the entire right lung and the uncollapsed portion of the left lung were filled with blood. Parts of this were of an almost solid consistence, practically consolidated, other parts were more fluid — a hemorrhagic lung with pulmonary edema.

Microscopical examination showed massive hemorrhage into the alveoli and rather minimal inflammatory reaction. There was some fibrin, some foci of hyaline membrane lining the alveoli and a beginning exudation of polymorphonuclear leukocytes. The inflammatory reaction looked more as if it were a reaction to hemorrhage than if it were primary. I am inclined to interpret this as a form of extremely severe pulmonary edema or

pneumonitis, which we do see from time to time in cases of active nephritis. I have seen it most often in cases of sulfonamide injury to the kidney, but I am quite sure that I have seen it in glomerulonephritis on a number of occasions as well. Whether there actually exists an entity that we call pneumonitis I am not sure. I have been tempted sometimes to think that there might be one. The picture is both grossly and histologically very similar to what is seen in a certain number of cases of acute rheumatic fever and ordinarily called acute rheumatic pneumonitis. I do not believe I can differentiate the two on the microscopical slides.

DR KING There is a hemorrhagic form of pulmonary edema with hemoptysis?

DR MALLORY Yes, one sees it occasionally.

DR KING It is rare.

A PHYSICIAN Were there any casts in the urine?

DR JAMES DAVIS Two urine specimens were searched for casts, but we found none — only red cells.

A PHYSICIAN Were there any lesions in the ureter?

DR MALLORY No.

A PHYSICIAN How are the skin lesions accounted for?

DR MALLORY Purpura is not rare with renal insufficiency. I would assume that that was the cause of it.

DR HARWOOD Gairdner reports a specific pathologic picture in Henoch's purpura as opposed to other kinds of bleeding in the skin, it might be interesting to know what the skin lesions showed histologically.

DR MALLORY The skin lesions were not examined. One frequently discovers that skin lesions that are conspicuous during life are hardly visible by the time of autopsy. Unless our attention is specifically called to them, we are apt to miss them.

DR ZAMECNIK Is there a pathological distinction in the kidneys between acute glomerulonephritis and purpura?

DR MALLORY I think there would be no question about that. I see no reason why one should have active lesions — the crescent formation and so forth — in purpura.

A PHYSICIAN Did the blood pressure go up?

DR MALLORY No, not in the period of observation. Of course that is unusual for glomerulonephritis, I must admit.

A PHYSICIAN Was there any lesion in the spleen?

DR MALLORY No, in the bone-marrow sections the megakaryocytes showed an unusual amount of pyknosis and degenerative change. Otherwise the bone marrow was not normal, it was a little hypoplastic.

## DOWN EAST DOCTOR

MARY ELLEN CHASE, professor of English at Smith College, is a coast of Maine New Englander, a product of the sturdy traditions and the independence of that particular rock-bound section of the country's shore line. That she should read the Aphorisms of Hippocrates in the original Greek or deliver the address at the annual dinner of the Massachusetts Medical Society is no more unusual than that she should have grown up and left the region of Penobscot Bay to teach English in a leading woman's college. Women of the Maine coast are accustomed to doing a day's work in fair weather or foul.

Professor Chase's recollections of the character and activities of a country doctor a generation

ago will stir nostalgic memories in many who read her address in this issue of the *Journal*, for it deals with a period and a place whose spirit is that of hardihood and self-reliance and personal independence. The smells of harness leather and the grain bin still linger in the nostrils of many of her countrymen who have not yet passed their active years, other ancillary facilities of transportation contributed to the "smell" of the doctor, as Miss Chase so nicely phrased it — the carriage lap robe, sun-cured hay and, at times, that Augean aroma that characterizes certain phases of the nitrogen cycle conspicuously identified with hooved animals. There are frontiers, too, where cold drawn castor oil and sweet spirits of niter are still in daily use, and the onion poultice has been professionally applied within the memory of living man.

The costs of medical care rarely constituted a problem in the country districts a generation ago, — Miss Chase's family spent \$105 for medical care over a period of sixteen years, — and pay was likely to be in "kind" — in labor or lobsters, a load of wood or a barrel of potatoes. The practice of medicine was not entirely a profession, it was a way of life, as farming once was, and a kindly one.

Miss Chase's reminiscences furnish something besides entertainment, they are more than a pleasant interlude in one of memory's lanes. They are a reminder that the medicine of today, if it is to be effective and economical, must be brought to the patient through the medium of one who is both counselor and friend. More and more, as life becomes increasingly complicated and the science of medicine more intricate and more costly it is apparent that the resourceful family doctor must remain as the backbone of the profession. Medicine in its relation to its public and in the service that it can economically deliver will be on firmer ground if the family doctor is encouraged to resume his former pastoral position.

The greater the complexities of medical science and the greater the need for specialization on that account, the greater also is the need of the patient for wise and kindly guidance. If the family practice of medicine should disappear, a great loss would be sustained. Such a loss would also mean that a type of life in which these values were appreciated had gone.

## POLYMYXIN

THE almost universal tendency of streptomycin to give rise to resistant organisms, its significant toxicity and its relatively low activity against many common pathogens have resulted in a very intensive search for new antibiotics to replace streptomycin in the fields in which it has proved its greatest use—namely, against gram-negative bacilli and in tuberculosis. At least one agent, highly active against gram-negative bacilli, has become available and is having some clinical trials. This agent has been obtained in two separate laboratories<sup>1, 2</sup> in this country from several strains of *Bacillus polymyxa* and a very similar if not identical substance was obtained in England<sup>3</sup> from a related organism, *B. aerosporus*. Interestingly enough, the findings in all three laboratories were announced almost simultaneously.

The preparation, named polymyxin by the workers at the American Cyanamide Company and aerosporin by those of the Wellcome Laboratory, has interesting properties.<sup>2, 4-7</sup> It is a basic substance obtainable in the form of crystalline hydrochloride and is water soluble. Its activity is not affected by reactions between pH 2 and 7 and is only slightly affected by blood, serum or other mediums at physiologic ranges. Polymyxin is effective against a number of important gram-negative bacilli including brucella, salmonella, *Haemophilus pertussis*, *Eberthella typhosa* and *Escherichia coli*. It is active in low concentrations more like those of penicillin rather than those of streptomycin within their respective fields. It is not active against gram-positive organisms, fungi or mycobacteria, and most strains of proteus are not inhibited. It is active in mice when given subcutaneously against infections with *Klebsiella pneumoniae*, *H. pertussis*, *Salmonella typhi*, *H. influenzae* and *Brucella bronchiseptica*, and it is also effective against fowl typhoid in chicks. It is not effective orally, but when given by this route, it results in replacement of sensitive by insensitive organisms in the feces.

Polymyxin is relatively nontoxic, but the hydrochloride may produce local irritation, and there is some evidence of a histamine-like contaminant

and possibly renal tubular damage from some preparations except possibly those that are highly purified. Resistant strains are not obtainable by the methods that readily produce streptomycin-resistant organisms, but resistance may be increased in vitro by serial passage, though much more slowly than with streptomycin. No morphologic changes result in the organisms. Polymyxin is equally effective against streptomycin-sensitive and streptomycin-resistant strains, and, contrariwise, streptomycin is equally active against strains made resistant to polymyxin as against their parent strains.

The action of the agent is apparently very rapid and is considered to be bactericidal at least when adequate concentrations are used. It is apparently well absorbed from parenteral routes but seems to have a high renal threshold.

Only one published report of the use of aerosporin in England is available.<sup>8</sup> The agent was used in the treatment of 10 cases of pertussis, and though the author appeared to be enthusiastic about the effects, the results as reported are difficult to interpret and are certainly far from convincing. There was some evidence of renal toxicity, and coexisting urinary-tract infections did not seem to be influenced favorably.\*

Obviously, more data are necessary before evaluation of this compound or of these agents, if they are different. The effectiveness and toxicity in further clinical trials of pure preparations are therefore being awaited. The only other intimation of beneficial effects in a number of infections in human beings is a brief mention of cases of infections due to *Pseudomonas aeruginosa*, *K. pneumoniae*, *H. pertussis* and *B. abortus* in which there was definite evidence of the therapeutic effectiveness of polymyxin.<sup>9</sup>

It is obvious that a better agent than streptomycin is needed in the treatment of infections due to the Friedländer bacillus, salmonella, brucella, pertussis and other gram-negative organisms. It will also be of interest, in view of preliminary indications of the high renal threshold, to know whether this agent is effective in the treatment of urinary-tract infections. The possibility of the development of resistant strains during treatment

\*A preparation called polymyxin B has recently been made available for clinical trials and is alleged by the manufacturer to be free of toxic effects on the kidneys.

## DOWN EAST DOCTOR

MARY ELLEN CHASE, professor of English at Smith College, is a coast of Maine New Englander, a product of the sturdy traditions and the independence of that particular rock-bound section of the country's shore line. That she should read the Aphorisms of Hippocrates in the original Greek or deliver the address at the annual dinner of the Massachusetts Medical Society is no more unusual than that she should have grown up and left the region of Penobscot Bay to teach English in a leading woman's college. Women of the Maine coast are accustomed to doing a day's work in fair weather or foul.

Professor Chase's recollections of the character and activities of a country doctor a generation

ago will stir nostalgic memories in many who read her address in this issue of the *Journal*, for it deals with a period and a place whose spirit is that of hardihood and self-reliance and personal independence. The smells of harness leather and the grain bin still linger in the nostrils of many of her countrymen who have not yet passed their active years, other ancillary facilities of transportation contributed to the "smell" of the doctor, as Miss Chase so nicely phrased it — the carriage lap robe, sun-cured hay and, at times, that Augean aroma that characterizes certain phases of the nitrogen cycle conspicuously identified with hooved animals. There are frontiers, too, where cold drawn castor oil and sweet spirits of niter are still in daily use, and the onion poultice has been professionally applied within the memory of living man.

The costs of medical care rarely constituted a problem in the country districts a generation ago, — Miss Chase's family spent \$105 for medical care over a period of sixteen years, — and pay was likely to be in "kind" — in labor or lobsters, a load of wood or a barrel of potatoes. The practice of medicine was not entirely a profession, it was a way of life, as farming once was, and a kindly one.

Miss Chase's reminiscences furnish something besides entertainment, they are more than a pleasant interlude in one of memory's lanes. They are a reminder that the medicine of today, if it is to be effective and economical, must be brought to the patient through the medium of one who is both counselor and friend. More and more, as life becomes increasingly complicated and the science of medicine more intricate and more costly it is apparent that the resourceful family doctor must remain as the backbone of the profession. Medicine in its relation to its public and in the service that it can economically deliver will be on firmer ground if the family doctor is encouraged to resume his former pastoral position.

The greater the complexities of medical science and the greater the need for specialization on that account, the greater also is the need of the patient for wise and kindly guidance. If the family practice of medicine should disappear, a great loss would be sustained. Such a loss would also mean that a type of life in which these values were appreciated had gone.

ens's London did not let their peg legs curtail their activities nor did the brilliant Confederate leader General Ewell reduce his mobility in the Shenandoah Valley on account of his. What a slap in the face for technocracy if all these modern prostheses dressed in new shoes and pants should languish behind the door except on state occasions! On thinking it all over, one finds it hard to escape the somewhat childish thought that a lot of waste motion could be saved simply by not blowing off peoples' arms and legs

### WHO RUNS MAY READ

THE *Lancet*\* comments philosophically on the replies made by twenty-five noted men and women when questioned on the subject What Life Has Taught Me. Each pupil learned a different lesson in this universal schoolroom, for, as Dean Inge pointed out, "life teaches us what we are capable of learning."

Tolerance for others in order to do a good job oneself is the lesson gleaned by one of these receptive students of life, respect for the individual is the text that another has acquired. Defined as a reluctance to inflict humiliation. Another finds logic in an immutable system of education that furnishes neither rewards nor punishments but only consequences.

The editor of *Punch* is pleased at finding that his countrymen value their sense of humor above wisdom, an eminent divine, deriving lessons from illness, "urges the invalid to be patient with doctors, who are amazingly nice when tamed." Still another student at life's bench deplores certain indications that the dweller in cities seems often to have no interest that warms life.

"The bravest of these commentators," the *Lancet* concludes, "have given us the best reading."

\*Annotations. Live to learn. *Lancet* 1 801 1948

### MASSACHUSETTS MEDICAL SOCIETY

#### DEATH

ROSMARIN — Ernest Rosmarin, M.D. of Boston, died on June 29. He was in his sixty-seventh year.

Dr. Rosmarin received his degree from Medizinische Fakultät der Universität, Vienna, in 1906.

A brother survives.

### A HUNDRED YEARS AGO

A bright morning sun on Wednesday last, gave promise of a pleasant meeting of the State Medical Society which was fully realized. Nearly four hundred medical gentlemen dined together at a spacious hall on Hudson Street, instead of Faneuil Hall as previously announced. The entertainment was elegant, and satisfactory we believe to all present. Last year the income to the treasury was \$1551.87 and the outgoes \$1038. About \$200 are now on hand. The permanent fund of the Society, securely invested in January next will amount to \$11,000. A large and respectable committee, consisting of one from each medical district in the State was raised to receive the delegates to the American Medical Association, who will assemble in Boston next year. A motion was made to authorize this committee to draw on the treasury for three hundred dollars. But this was voted down by an overwhelming majority, and a more lastingly mean act was never perpetrated by the Society. How is it possible to show the civilities of the Society or exhibit even a semblance of sincere attention, without the means of doing so? The plea was raised in extenuation that the Society was poor. Yet there is the sum of eleven thousand dollars at interest, which if sunk in Lake Superior Copper Stock, would not have been considered by some of the members so great a loss as that occasioned by this parsimonious act. A spirit of false economy saved the money while it disgraced the institution. Is it credible as was said, that the Massachusetts Medical Society never exhibited more vigor, enterprise and soundness of constitution, than at the present moment? — Through the influence and at the expense of a lodge of Odd Fellows in Boston, the community have been furnished with a printed lecture by Charles E. Buckingham, M.D., on *Circumstances affecting individual and public health*. If the Odd Fellows pass their evening conclaves in listening to instruction like this, it will be at once conceded that they are persons of excellent taste and judgment, who contemplate the sufferings of the afflicted with a view to administering to their relief. The spirited author has an independent manner of giving his opinion, which reminds us of the tense style of his father. Dr. B. is no friend to physic, unless it is positively indicated. After the simple manner of the prophet, he would have all men wash and be clean — breathe fresh air and be well. On the subject of sewerage, which is of immense importance in cities and appreciated in Boston more than in most other cities Dr. Buckingham is particularly emphatic. If the appropriate filth of sewers is suffered to run into the gutters of city streets working its sluggish way, and exhaling, as it goes, a pestiferous stench, the

must also be known before enthusiasm for this agent is engendered

### NEW FASHIONS IN WOODEN LEGS

MAN's mechanical ingenuity is a strange and wonderful thing. Not content with devising ever better methods for blowing off human arms and legs, he ceaselessly toils to perfect artificial means of replacing them. When, in the sixteenth century, bombards and hand-cannon came into more effective use on the battlefield, it probably appeared to contemporary observers that scientific progress was entering a deplorable time of inhuman destructiveness. It then took a doctor to turn science into a more humanitarian channel. In 1564 Ambroise Paré published his first account of artificial limbs with joints that worked by springs and ratchets.

As the science of destruction continued to advance, so also did the science of replacing limbs, but to a more modest extent. Ravaton, White, Addison, Wilson, Brunninghausen, Ruhl, Miles, Serre and others did their best to keep Paré's crude inventions abreast of the times. The recent bound forward that civilization has taken in the development of land mines, blockbusters and atomic explosions is now placing an unprecedented strain on humanitarian inventiveness.

It is reassuring to know, however, that the race is not being abandoned. On May 13, 1948, the

armed forces, Veterans Administration and Committee on Artificial Limbs of the National Research Council held a demonstration of the newest prosthetic developments at the National Academy of Sciences in Washington, D. C. Not the least impressive feature of the Government's artificial-limb program is the list of high-powered names and agencies concerned. Though reminiscent of less immediately altruistic activities, such names as Vannevar Bush, Robert Patterson, Northrop Aircraft, Wright-Patterson and Naval Ordnance Laboratory assure at least the degree of scientific competence that was directed toward producing amputees on so large a scale.

The devices now ready for field testing prior to general production and distribution are as far ahead of Paré's as the atomic bomb is ahead of the bow and arrow. "Some involve rather radical principles of design," according to the official report. For example, a prosthesis for above-the-knee amputations incorporates "control of knee flexion by a hydraulic cylinder with unbalanced valve activated by muscle control." "Coordination of knee and ankle motion includes initial knee flexion on heel impact with partial knee extension during the load phase (due to a crossed linkage including the hydraulic cylinder) as well as toe pickup during the swing phase (due to a rod with hydraulic slip joint)." In another, "control of knee flexion is provided by a vane-type hydraulic snubber with valve closed by pressure on rear half of foot regardless of ankle position." Full advantage has been taken of flexible plastics to produce artificial hands of naturalistic appearance whose mechanism permits "fast fanning of fingers until they press the load against the thumb, then engagement of a force multiplier for increased grip" and an "automatic lock with anti-backlash device driven by the single control cable."

There can be no doubt about the technologic triumphs represented by these exhibits. How well they will all serve the needs of their recipients remains to be seen. Apparently, Paré had mental reservations concerning some of his own devices because he included the simple design of a peg leg, as he says, "for poor people." Certainly Long John Silver on Treasure Island and Silas Wegg in Dick-

health of no one can remain safe, within the reach of its baneful influence. A new impulse has been given to the great inquiry — how shall apartments be supplied with pure air? No wonder that the victims of pulmonary consumption are multiplied to a fearful extent in New England, where close sleeping apartments, air-tight stoves, and almost air-tight rooms, are considered necessary to everyday comfort. A profound sense of the destruction of life from these and kindred sources, is happily manifesting itself by the public generally, as well as by influential individuals, so that the hope of a better sanitary constitution of society may reasonably be indulged. While thanking Dr Buckingham for this strong argument in favor of reform, the lodge of Odd Fellows are entitled to the gratitude of all who are not odd, for their kind intentions in giving publicity to the discourse — A kind of ring mania is existing in New England. It is enough that a penny paper advertisement declares that Dr Cristy's Galvanic rings are a positive remedy for human maladies and many weak-minded people not only cover their fingers and neck, but their toes, with metallic hoops, which they imagine are charged with extraordinary medical powers. It is certain, however, that Dr Cristy has no right to claim the practice of this nonsense, as his own discovery. It seems that in 1812 *galvanic beads* were all the rage in Boston, promising to accomplish nearly the same blessed results expected to flow from the more recently devised galvanic rings — Another pamphlet on *The Ether Controversy* may soon be expected. Report says that Mr Bowditch, one of the trustees of the Massachusetts General Hospital, is the author. The contest is likely to be perpetuated while the several claimants to the honor of having discovered the value of ether inhalation continue able to write and publish — One of the anomalies of the present day, is the radicalism of practitioners of medicine. The community rings with the whims and caprices of those whose vocation is to interpret the language of nature, and medical schools are as much at variance with each other as individual practitioners. This creates confusion, engenders distrust in the public mind and lessens the confidence in those educated expressly to minister to human maladies. Indeed, there is an elevated class of citizens who countenance quackery in its thousand protean forms, because of the non-agreement of physicians, their radicalism and their want of confidence in the resources of medicine — Extract of dandelion is becoming a new article of domestic manufacture. The dandelion possesses a medicinal value far above the estimate often placed upon it. As a detergent and aperient, and especially as a diuretic, it might well take the place of some other articles in use — The approved modern treatment of acute gout has become well standardized. It should com-

mence with a purgative, which may be a smart one if the patient is robust and plethoric — from ten to twenty grains of jalap, and from three to eight of calomel, followed in from two to five hours with a draught, consisting of equal parts of the infusion of rhubarb and senna, containing a drachm of sulphate of potass, and a scruple of that alkali. After this, a diaphoretic tisane, consisting of one or two drachms of ipecacuanha wine and four drachms of the solution of acetate of ammonia, in a pint and a half of weak tea, is to form the patient's drink. The patient is to eat little or nothing for twenty-four hours. At night, a full dose of Dover's powder may be given. This will relieve pain, secure sleep, promote diaphoresis — each an important object. On the third day, the use of colchicum may be begun. It is efficacious when given simply in doses of from twenty to sixty drops of the wine in four or six ounces of distilled water, along with from five to ten grains of the nitrate of potass. To this, two drachms of the compound spirit of juniper, and a half a drachm of the spirit of nitric ether may be added. Few persons can bear or will require a dose of sixty drops of colchicum wine oftener than twice in the twenty-four hours. Many cannot endure a half or third of that quantity — Extracted from the *Boston Medical and Surgical Journal*, June-July, 1848

## NOTICES

### NEW YORK POST-GRADUATE HOSPITAL RESEARCH FELLOWSHIPS IN MEDICINE

Two appointments for research fellows in medicine for studies in the field of metabolic and degenerative diseases are available in the New York Post-Graduate Hospital immediately. Opportunities for ward studies, postgraduate courses and outpatient clinics are included. The salary is \$3000 per annum.

Graduation from Grade A medical school and three years of approved hospital training in medicine and allied fields are required. Male and female applicants are acceptable. Applications should be addressed to Dr John D. Currence, New York Post-Graduate Medical School and Hospital, 303 East 20th Street, New York 3, New York.

### NEW ENGLAND SOCIETY OF ANESTHESIOLOGISTS

A meeting of the New England Society of Anesthesiologists will be held in the auditorium of Building A, Boston University School of Medicine, 80 East Concord Street, Boston, on Tuesday, September 14, at 8 p.m.

A scientific program will be presented by the Boston City Hospital Group.

#### PROGRAM

Symposium on Anesthesia for Thoracic Surgery  
 Variations in Induction for Intubation Dr Sidney C Wiggin  
 Management of Positive Pressure Dr Peter Saunders  
 As the Surgeon Sees Anesthesia for Thoracic Surgery Dr John W. Snieder  
 Control of Cardiac Arrhythmia and Ventricular Fibrillation Dr Dwight E. Harken  
 Physicians and medical students are invited to attend

## USE OF THE VAGINAL SMEAR AS A SCREENING TEST\*

HERBERT L. LOMBARD, M.D.,† MARGARET MIDDLETON, A.B.,‡ SHIELDS WARREN, M.D.,§ AND  
OLIVE GATES, M.D.¶

BOSTON

IN VIEW of the current interest in the vaginal smear and the optimistic hopes aroused by recent accounts of its usefulness, a preliminary report of a study being made by the Massachusetts Department of Public Health to evaluate the method may be helpful in clarifying its present status as a diagnostic test.

The technic for the detection of uterine cancer by means of vaginal secretions was first described by Papanicolaou<sup>1</sup> in 1928. In 1943 Papanicolaou and Traut<sup>2</sup> presented evidence of the value of this method for demonstrating carcinoma both in patients before symptoms had appeared and in those in whom clinical examination and biopsy had failed to reveal the presence of a carcinoma that was extensive enough to produce symptoms. At the same time Meigs and his co-workers<sup>3</sup> reported an original investigation along the same lines, with similar favorable results. In this publication the authors pointed out the possible usefulness of the smear as a routine diagnostic test and suggested that the diagnosis of vaginal smears should be available to all physicians through the Massachusetts Tumor Diagnosis Service.

In spite of general interest arising from these and a number of confirmatory reports by different workers during the past four years, the use of the method has been limited, owing in large part to difficulties of interpretation of smears and the time and training required for competence in diagnosis. The pressure of public demand resulting from recent publicity of the vaginal-smear technic has prematurely forced an answer to the question of its practicability both as a routine diagnostic method and as a screening test. The crux of the

problem rests on the facts that diagnosis of smears requires wide experience and much time and that only in exceptional cases does the smear give information unobtainable by clinical examination and biopsy.

It should not be supposed that an experienced pathologist or cytologist can successfully undertake the interpretation of smears without acquaintance with the manifold variations of the structure of exfoliated cells in cases of pelvic disease and neoplasia. Accuracy of interpretation depends primarily on a familiarity with the aberrations of cells in benign and malignant states. Fortunately, a medical or scientific background is not essential for acquiring this knowledge, which may be obtained by diligence and careful observation correlated with clinical information. It will take from four months to a year to gain proficiency in this type of diagnosis, depending on aptitude and richness of material available for study.

Despite the initial difficulties and expense involved in the diagnosis of smears the method appears to be peculiarly suited for large-scale use. The limiting factor at present is the availability of technical skill. The cost per specimen varies, according to the volume, from \$1.50 to \$5.00. Once the necessary training has been gained, a technician can read between twenty and forty smears a day. The specimen can be obtained by relatively unskilled personnel without discomfort or inconvenience to the patient. If symptomless cancer can be demonstrated in an appreciable number of cases, the vaginal smear is an economical and practical method for use in cancer-detection clinics.

With these considerations in mind, a long-range experimental study financed by the Commonwealth Fund was inaugurated in Massachusetts in January, 1945, by the Department of Public Health to determine whether this test is of sufficient value to warrant its use in the cancer clinics either as a screening test to detect symptomless carcinoma or as a routine diagnostic measure for all gynecologic cases and, secondly, whether it should be offered
